Bombay.—The number of municipalities in Bombay in 1898, excluding Bombay City, was 166, or one less than in the previous year, two municipalities, Matar, in Kaira, and Pussesavli, in Satara, having been abolished, and only one new municipality, Kharda, in Ahmednagar, having been established. The aggregate income in 1897-98 was £355,080, a decrease as compared with the preceding year of a sum not far short of £40,000. Not only was the income less, but the proportion allotted to sanitation showed a large decline, from 57·21 to 49·23 per cent. of the total. The actual sums expended were, on water-supply, £34,534, against £60,527 in the previous year ; on conservancy, £70,051, against £98,507, and on improvement of sites, £8,129, against £11,406. The expenditure on miscellaneous sanitary work, including the construction and repair of tanks, was nearly trebled, rising from £15,890 to £44,177.

It is stated by the Sanitary Board that, owing to the heavy expenditure in connection with plague, the consideration of important sanitary improvements has been deferred in almost every municipality, and that unless Government come to their aid in relieving them of some portion of the debts contracted, sanitary work must be at a standstill for years.

At Shikarpur nothing was done to drain the town, and indeed the municipality has passed a resolution stopping the construction of a system of gutters, which would have removed some of the waste water from the town.

At Sukkur the water-works engines have been neglected, so that extensive repairs will soon be necessary.

At Sholapur the municipality still rely upon one engine to pump water, and, should it break down, the results will be serious.

At Satara, it is stated that the Municipal Commissioners consider it inconsistent with their dignity to allow the Government Engineer to supervise the miles of open channel from the Kas tank, although they are quite unable to supervise it themselves.

At Hyderabad, the municipality was induced to order new engines for the river pumping station ; and plans and estimates for completing the water-supply project have been prepared. The committee obtained plans and estimates for a satisfactory drainage system, but the scheme has been shelved.

At Ahmedabad, the plans for the remainder of the drainage scheme have required some modification, but the municipality has applied for permission to raise a loan of eight lakhs (£53,334) of rupees to carry out the work

At Kaira, a new water-supply scheme, to cost £5,334, has been sketched out.

At Yeola, there is great delay in carrying out the water-supply scheme, due, seemingly, to delay in receipt of the necessary materials.

At Ahmednagar, the water-supply question is becoming acute. The town is situated upon a high table-land subject to recurring deficiency in the rainfall. Not only is the rainfall precarious, but, for some reason, the level of the subsoil water has been steadily falling for the last ten or fifteen years ; this affects the wells of course, and also the old aqueducts upon which the town relies for its supply of water. The only solution of the question, it is said, is the completion of the Kapurwadi tank, at a cost of about £10,000.

At Kirkee, the water-supply project has been nearly completed.

At Poona, the Sanitary Engineer has been directed by Government to prepare comprehensive drainage schemes for the city and for the adjoining crowded *sadar* and Sholapur bazars.

At Akalkot, the water-supply project, which is being carried out under the supervision of the Sanitary Board, was rapidly approaching completion ; and it was hoped that the engine would be at work within less than a year of the date when final sanction to the scheme was accorded.

Like the municipalities, the district boards suffered a decline of their income, which fell from £276,384 in 1896-97 to £256,146 in 1897-98. The sanitary allotment was reduced from £57,604 to £47,479, of which £41,901 was set aside for, and £27,662 actually spent upon, water-supplies.

The Village Sanitation Act was introduced into 17 more villages, making 299 in all ; while village sanitary inspection books are in use in 3,199 villages, although, owing to the disorganization of ordinary sanitary work in the face of plague, but little progress has been made in filling them up.

The constitution of the Sanitary Board remained unchanged. The number of meetings is not stated, but the members are apparently in continuous communication with each other, and much useful work was done by them during the year, to some of which, and the most important, allusion has been made above. The Board again approached their Government with a view to having executive powers conferred on them, but the Government of Bombay are not at present prepared to alter the rules governing their duties and powers.

Burma.—The income of the towns and districts in Upper and Lower Burma in 1898 was £451,766, and nearly 33 per cent. of this, or £148,027, was spent on sanitary improvement of one kind or another ; although, as pointed out by the Sanitary Commissioner, many of the other "sanitary works," which absorbed £54,216, have a very indirect bearing on sanitation. The sum expended under this heading is, however, more than £10,000 less than in 1897, while the expenditure on water-supply has increased from £16,076 to £26,056, and that on drainage from £7,987 to £27,255. On conservancy the expenditure fell from £54,154 to £40,508.

No sanitary undertaking of capital importance was begun during 1898, but the newly appointed Sanitary Engineer took up his office in January, and was very fully occupied throughout the year. A survey for water-supply works at Moulmein was completed, and plans for a gravitation project, estimated to cost £57,618, were submitted to the Chief Engineer. A preliminary survey was made of Bassein, and a report was made on the Kanthaonzin lake project for its water-supply. Mandalay and Meiktila were visited, and reports on their water-supplies submitted ; a project for the water-supply of Meiktila, at a cost of £8,829, being reviewed. The project prepared by the Executive Engineer of the Southern Shan States for the water-supply of Kengtung was thoroughly examined, and returned with suggestions for revision.

The plans and estimates prepared by the Municipal Engineer for the Prome drainage scheme were examined and returned for revision.

Village sanitation seems to make progress in some places, but in others the matter does not receive the attention from the district officials that its importance deserves.

"The Sanitary Board did practically no work during the year."

General Remarks.

The Red Sea Pilgrim Traffic.—The number of pilgrims who arrived at the Camaran quarantine station during the winter and spring of 1897-98, and who were there detained for observation prior to proceeding to Jeddah for Mecca for the Haj of the year under review, was 15,228, against 14,210 in 1897. Of the total, only 1,014 were registered as coming from Indian ports, *viz.*, 890 natives of India and 124 Afghans, while in 1897 these numbers were, respectively, 2,493 and 327.

As regards India, the way to the Hejaz was practically closed during 1898, by the prohibition issued by the Government of India on February 20th, 1897, which suspended the pilgrimage for that year; but this order was subsequently modified in a Notification (November 20th, 1897) by the same authority, to the extent of permitting persons, not being permanent or temporary residents of the Bombay Presidency, excluding Sind, to embark at Karachi or Chittagong, the necessary precautions being taken for the preliminary medical observation of the intending pilgrims. At the same time the Government advised all concerned to refrain from taking advantage of the concession, in view of the stringent quarantine regulations imposed by the Turkish Government, and the consequent inconvenience thereby entailed on Indian pilgrims on arrival in Arabia. A quarantine camp was accordingly established at Chittagong, and 730 pilgrims, who arrived for embarkation, were there detained for observation, and of these 708 were ultimately allowed to proceed on board the s.s. "Jubeda," which left that port on February 16th. Subsequently, on November 10th, 1898, the Government of India further ordained that no person resident in the Bombay Presidency (excluding Sind, but including its port, Karachi), the Madras Presidency, Mysore, the Hyderabad States, and Coorg, would be permitted to embark for Mecca from any port in India, save Chittagong, and then only after a period of detention for medical observation. Intending pilgrims were, at the same time, again advised to defer their journey until a more favourable season.

As subsidiary measures, and prior to the order last noted, special arrangements were made to ensure that pilgrims passing through Baluchistan should be conveyed by train, in reserved carriages, to observation camps before they were permitted to embark from Karachi; and further, authority was given to the Bombay Government to issue any necessary orders under the Epidemic Diseases Act in connection with the arrival of pilgrims from the Madras Presidency, who would be likely to require transhipment at Bombay *en route* to Karachi.

As regards Bombay, no vessels with pilgrims for Mecca left the port during the year, and from only one port in the Madras Presidency, *viz.*, Malabar, was a ship despatched, and this vessel left on March 8th, carrying 207 pilgrims. So far then as can be accurately ascertained, only two ships left Indian ports in this traffic, the total number of pilgrims conveyed being 915. It is satisfactory to record that no case of cholera or plague occurred during the outward or homeward voyages, nor at Camaran, where Indian pilgrims were detained for ten days prior to their departure for Jeddah.

Return of the Pilgrims.—During the year 1,342 pilgrims returned from the Haj to Bombay *viâ* Aden and other ports, and these were conveyed in six ships, which made altogether eleven trips between and including the months of April and November. In order to obviate the danger apprehended from the mixing of the pilgrims with the towns-people, the arrangements which had been successfully carried out in 1897 were again resorted to. The pilgrims were not allowed to enter the town, but after disinfection of their effects, were sent direct from the ship to the railway station, and thence, by batches, in special trains to their destinations, the local authorities concerned being advised of the despatch of each train.

During the return voyage, five cases of infectious disease were recorded, all of small-pox; in all six deaths occurred: four from chronic dysentery, one from small-pox, and one suicide. At no other port in India were returning pilgrims disembarked.

As regards the health of the pilgrims, the arrangements made for their control and comfort at Jeddah and on the journey thence to Mecca and back, nothing can be recorded here, as the usual report has not been submitted.

Jigger.—The expansion of the Empire, and the development of inter-communication of its component parts, has had for one of its consequences the risk of affording an open door to the invasion of India by the Chigger or "Jigger" pest. The Jigger (*Pulex*

Penetrans) is indigenous to South America and the West Indies, but obtained a foothold on the West Coast of Africa early in the "seventies," where it is said to have been landed in sand ballast from a ship from Brazil. Its gradual spread from the coast was slow at first, and confined to the dry sandy tracts, but as the interior was opened up by the several expeditions of explorers and traders, the jigger was carried more rapidly throughout Central Africa, traversing the whole breadth of the continent in the lines of the trade routes. Extended references to its distribution and clinical effects in Central Africa will be found in the accounts recently published by travellers in this region, and their statements are amplified and independently confirmed by Captain Haig, I.M.S., the medical officer in charge of the 1st Battalion Uganda Regiment. In an interesting note on the subject, after describing the insect and the conditions which favour its existence outside the body, the clinical symptoms and course, and the ultimate disability that often follows the access of the impregnated female to the vascular layer of the skin, Captain Haig lays stress on the following points, which have an epidemiological interest.

After referring to the well-accredited assertion that the pest, originally confined to South America, was conveyed thence by a ship to the West Coast of Africa, the fomites in this case being sand ballast, which was discharged at the port of arrival, he notes its early confinement to the dry sandy tracts, with very slow and gradual dispersion. With the opening-up of the interior by explorers and traders, there was an extraordinary dispersion of the pest, its progress being easily traced as *pari passu* with the advance of the various lines of communication, until from the lakes to the coast on both sides it now swarms over Equatorial Africa. But with this there is an apparent confinement to a certain restricted zone, roughly equatorial in general, but locally dependent on the drier and more sandy soils. It remains to be seen what effect the extension of communications north and south will have on its dispersion. "They cannot withstand moisture, and sprinkling the floor of a house with water drives them away."

While chiefly dependent on human hosts for progress to pastures new, and to some extent for propagation (though many of the lower animals serve this purpose, and some warm-blooded animal seems to be essential for the period of gestation of the female), yet the insects appear to be able to survive for a considerable but undetermined period away from the neighbourhood of men or animals. Captain Haig further lays stress on the great value of habits of personal care and cleanliness as affording the one effectual means of preventing its disabling effects. The necessity of daily routine examinations of the feet (and of other parts of the body which have been in contact with the ground, *e.g.*, the elbows and buttocks) is strongly insisted on, and an instructive contrast is drawn between the clean and intelligent people of Uganda and the Masai tribes, who are said to be dirty and savage, in respect of the almost entire immunity of the former to the ravages of the insect, while the latter suffer terribly for their neglect. "Numbers of these people (the Masai) die from blood poisoning, the result of jigger ulcers." Again, "the sepoys of the Uganda Regiment used to be laid up frequently owing to jiggers, but now that they have learnt to examine their feet regularly they do not suffer at all." In this way the penetration of the impregnated female is prevented, but at a later stage the excision of the gravid insect and its destruction by fire will obviate the propagation of the pest. Lastly, another observer, Captain Kilkelly, I.M.S., who was in charge of a native regiment returning from Mombassa to Bombay, *viâ* Aden, has found that a period of from two to three weeks is required, from the time of the entry of the pulex into the tissues to the approximate time of ovulation, a fact which should secure the detection of cases in passengers from the East Coast of Africa to any Indian port. That the pest can, however, be introduced into new territory widely separated by sea from its present habitat, by incorporation in a human host, is shown by recent experiences in Bombay, where patients coming from Africa have been admitted to hospital.

The foregoing has its general interest in the fact that we have here a picture of an endemic disease becoming epidemic in the sense of its spreading widely and attacking the majority of the inhabitants of large and widely separated areas, but apparently always under the limiting conditions of the life requirements of its cause, an instance of the truth that epidemiology is a branch of natural history. As regards the endemic areas, where the cause is one of the natural fauna, our safeguards lie in certain preventive measures; outside these areas, although the parasite may be introduced, its propagation and extension will depend on whether the environment be favourable or unfavourable to the requirements of what may be called the saprophytic stage of the organism.

India has long had constant and frequent communication with South America and the West Indies on account of the rice and coolie traffic, but there is no record of the introduction of the jigger by this means. More recently the connection of our West Coast

ports has become much closer with the East Coast of Africa, and it was owing to the reports of the widespread nature of the pest, and of the grave disabilities it inflicted, that the Government of India were moved to take precautions for the prevention of its introduction into this country. The Governments of Madras, Bombay, Bengal, and Burma were accordingly addressed upon the subject, and the adoption of the following precautions was ordered. Periodical inspection and careful treatment of all Indian coolies employed by Government in British East Africa or in other parts of the continent having direct communication with Indian ports; medical inspection of all persons leaving East African ports for India, and the prohibition of embarkation for India of those suffering from jigger; medical examination on board ship of passengers for India with the object of detecting cases infected shortly before embarkation, and which may have developed on the voyage; careful medical inspection at the port of debarkation in India of arrivals from Africa, and detention for treatment of all cases of jigger, in which the parasite had not already been extracted or destroyed. It was also arranged that advice should be given to natives in whom the parasite might develop after leaving Bombay and arrival at their homes, as to the nature of the disease and the necessity of early recourse to a dispensary for treatment. Where ships contained cases, washing down with kerosine oil was advised, and the ballast was to be discharged into the sea.

These precautions have so far been justified at each step, and the first alarm of a real danger to India of the introduction and dispersion of the jigger, though justifiable, was probably exaggerated. The timely warning received and the knowledge spread of the chief safeguards to be adopted, which may be summed up as personal care and cleanliness, have most probably secured us against one more scourge. But beyond this it is doubtful if the damp coast districts of India, to which the parasite would first be brought, are suited to the development of its larval stage; it is beyond doubt that jiggers must, previous to the warning of late in the year under review, have been carried into India by returning coolies or others, but, so far as is known, without establishing a foothold.

For the rest it appears probable that the great range of temperature, and the monsoon conditions to which the greater part of this country is liable, would prove inimical to its naturalization.

Disposal of excreta; the Sewage problem.—The effective removal and disposal of excreta in this country have ever been a standing problem for the sanitarian, and it is one that, in the very diverse circumstances under which the different communities live, affords little prospect of a final and comprehensive solution. Out of a total population of some 300,000,000 persons, 90 per cent. dwell on the land in villages, the majority of which can only be visited at long intervals by a sanitary authority, and where ignorance and primæval custom in these matters give consent to that individual freedom of action which prevailed anterior to the Mosaic code. Hindus maintain a high standard of personal cleanliness, but their ignorance and the trammels of custom make it very difficult to introduce sanitary improvements.

When we come to the towns and cities the difficulties and dangers are increased, for the native retains much of his ignorance, and clings to his customs, and what is effected by sanitary ordinance is but a more or less satisfactory compromise as far as removal of excreta is concerned, while the difficulties of disposal are greatly enhanced. This will be more clearly understood when the fact is grasped that, save in some half-dozen of the largest towns, no system of sewerage proper obtains, and the very general arrangement is for the night-soil to be removed by hand from the private dwelling and the public latrine, to spots set apart on the outskirts of the town, where it is commonly deposited in pits (from which it may or may not be removed after some months for use as manure), or it is trenched. Waste water (sullage) is dealt with separately; as a rule, it trickles out of the houses and is carried off by surface drains to discharge into "tanks" or a convenient "*nullah*," or to a river. This is a point of great importance in view of any scheme of disposal. The native population uses an extremely small quantity of water for all domestic purposes, for while the average consumption per head in large English towns is about 33 gallons daily, it is probable that the native of India finds all his needs supplied by one or two gallons (excluding that for his cattle). It will now be evident that sewage, as the term is used in Europe, does not and never will exist in India, except under very exceptional circumstances, in a few large cities, with a water-supply on modern lines, and in cantonments for British troops, when treated apart from any large native community in their neighbourhood. As Farr said, "a system of sewerage is the necessary complement of a water-supply"; in the absence of the latter, save that obtained from a number of disconnected wells, the former has found no place in

our plan of operations. Of recent years, however, the situation has been entirely changed in certain of the larger cities and towns by the introduction of that very factor, and we consequently find these more advanced communities face to face with the problems of disposal which have exercised English sanitarians during the last half century, or rather since the introduction of the water-closet in 1828-33. And it may be briefly stated that, in the search for a means of disposal, the sewered towns in India have followed the example set in England. Bombay endeavours to discharge its excretory refuse into the sea, as is the case with Rangoon, where the "Shone" system of removal has long been in satisfactory operation. In Ahmedabad and Karachi, after certain difficulties of detail had been met and overcome, broad irrigation, with subsequent cultivation, has been successfully carried out. The Calcutta sewage is conducted to an outfall into the Salt Lakes, five miles east of the city; that of Benares is discharged into the Ganges, while that of Simla finds its way into a mountain water-course.

In cantonments, the system of disposal varies according to the site and the available land. The night-soil is removed by hand or cart, or, in a few instances in some hill stations, by wire tramway, to a suitable site where it is deposited in pits, or is trenched. Here we see the "dry-earth" system under the most favourable conditions, but with results often not in proportion to the efforts put forth, and hence the resort, in many cases, to incinerators.

The problem of disposal is simply how best to hasten and ensure the natural processes of decomposition, the complete resolution into the original component mineral and gaseous elements or compounds of the food of animals and men, the final stages in fact of a decomposition already begun in the body. Many of the preliminary steps by which the complex organic molecule is naturally resolved into simpler compounds are doubtless of the nature of a hydrolysis brought about by enzymes in the absence of free oxygen (*e.g.*, insoluble albumens into peptones; urea into carbonate of ammonium), and this is a point of some importance in connection with the dissolution of the excess of suspended solids and extraneous rubbish (which is a prime characteristic of Indian sewage) in any method of biological treatment. But although the stages of complete purification are many and complex, the final result can only be obtained in one way, viz., by oxidation.

Oxidation may be brought about artificially by means of heat, naturally by the agency of microbes, either in presence of free oxygen or of reducible salts (*e.g.*, nitrate of soda); lastly by the vital action of living tissue-cells.

In the case of heat, oxidation may be—

(*a*) Complete, when the organic matter is entirely resolved, and no putrefaction products are evolved, implying a high temperature and free access of oxygen.

(*b*) Incomplete, when either by reason of the faulty construction of the incinerator, excess of moisture in the refuse or deficient fuel, the temperature is not sufficiently high, or oxygen does not obtain free access to all parts, and, as a result, partially decomposed products are given off, which, if not dangerous, are at least a very serious nuisance.

When we invoke the agency of microbes, the processes are analogous :—

(*a*) With abundant access of oxygen, and under suitable conditions of temperature and moisture, decomposition is complete, and there is not only no nuisance, but we have at our disposal a stock of available capital for replenishing our depleted soil and so maintaining the cycle of life.

(*b*) With deficiency of oxygen, or defect in the other necessary conditions, there is putrefaction with its drawbacks, if not dangers.

It is late in the day to re-affirm the great advantages and the superiority in every respect of Nature's method; but the artificial conditions created by the aggregation of large numbers of men on a limited area impose the necessity of furthering and assisting her efforts, which entails the exercise of care and judgment as to the form our assistance shall take in the varying conditions of the communities to be served.

The means of disposal in common use, then, are—

(1) Incineration.

(2) The discharge of the collected impurities into a water-course, sea or stream.

(3) The application to land, either by broad irrigation, by individual deposit on the surface, or by burial, more or less superficial.

(4) The new departure, or so-called "biological" methods now on trial in India as in England, in which the recognised agencies of the former methods (2)

and (3) are afforded fuller scope on a more favourable stage, and under more certain control. It remains to discuss briefly these various means of disposal, in the light of the conditions that prevail in this country.

(1). The destruction of valuable organic refuse by burning is purely artificial and altogether wrong in principle ; it entails immediate loss of the fixed nitrogen, so valuable an asset in the earth's economy. Besides this there is the cost and loss of fuel. To burn sewage is doubly wasteful in India, where both manure and fuel are scarce—the want of the latter re-acting on the scarcity of the former—because the people are driven to the use of cow-dung as fuel. Attempts have been made to render the process cheaper by using ordinary refuse to burn night-soil, but it is only rarely and under exceptional circumstances that the former is in sufficient quantity or sufficiently combustible to serve the purpose. In India the monsoon conditions militate against success in this respect, and as to the actual results, experience has shown that great nuisance (if not danger) from the evolution of partially decomposed products from lack of complete combustion is very general. The heaping up of night-soil to await combustion, where the incinerator capacity is insufficient, is another common source of nuisance and danger. Again the admixture of earth with the night-soil, as carried out in the dry-earth system, prevents combustion by heat ; incineration therefore involves the abandonment of the dry-earth system in latrines, with all its undeniable advantages. Lastly, this method fails to deal with the urine and slop-water, the larger part of the excretory refuse, and on this account alone it is sufficiently condemned.

(2). Where a sewered town is situated upon or near a river, the temptation to discharge its sewage into the stream has only too frequently been succumbed to, and while this method of disposal depends upon the chemical and, chiefly, the biological forces which the stream commands, the almost inevitable result has been to create a fresh and greater danger in the place of the one which it is the object to defeat. This of course refers to raw untreated sewage, which is commonly discharged in such amount, relative to the volume of running water, that the fauna and flora therein are unable to decompose it by the aid of the available oxygen (which is an uncertain and limited factor), with the most deplorable consequences to the river and to the health of the community. But the discharge into rivers of a "purified" effluent from sewage has come to be recognised as feasible and permissible, although the English sanitary authorities have not yet found themselves able to specify a standard of "purity." This is a question that the present Royal Commission may be expected to pronounce upon, with an approach to definiteness that has hitherto been impossible, and towards the solution of which the conclusions recently arrived at from the experiments carried out on the Manchester sewage and on the effect of the effluent obtained, upon the water of the Ship Canal, will materially assist.

The chief of the many methods devised to produce such "a purification" of the raw sewage are—

(*a*) The precipitation of the suspended, and an uncertain but small quantity of the dissolved, impurities by chemicals.

(*b*) The filtration of sewage through land.

(*c*) The new "biological" methods, similar in principle to the former, but not aiming at securing a profitable return.

Of the first it may be said that it is costly and only partially effectual ; the dissolved matters are but little affected, and the chief problem is untouched. The effluent is not prepared for further self-purification in a stream that may be used for domestic service.

Broad irrigation may be highly successful and even profitable, but it requires a large area of land, which within a certain range must possess certain characteristics ; the cost of land, of the necessary works, and of the skilled supervision are drawbacks, while the results as to the quality of the effluent are in many cases very questionable. Where good porous soil is available and cheap, at a convenient distance and at the proper level to be commanded by gravitation, broad irrigation may certainly be ranked in the first class of the means of disposal, where the sewage is not "heavy."

The "biological" methods of recent introduction are an adaptation of the principles of treatment by land filtration, and they depend upon the agency of micro-organisms, two broadly distinct stages being recognised in the entire process, just as has been shown to occur in the conversion of urea ; the products of decomposition varying with the different classes of organisms in action, and in the presence or absence of oxygen. Whatever the details adopted, the ends sought are attained by exposing the sewage to the action of the

micro-organisms with which it swarms, under conditions most favourable to their special functions, and ultimately, in all cases, in the presence of free oxygen. We can control the action of the micro-organisms to almost any extent desired; the area required for the treatment of large quantities of sewage and the expert supervision necessary are reduced to a minimum; climatic conditions, in the temperate and tropical zones, may be eliminated; a sewage, of almost any strength, may be adequately "purified"; and lastly, we retain the most valuable manurial elements, and as the chemical quality of the effluent is under control, we have the option of discharging it upon arable land, or into convenient water-courses. It must be admitted, however, that we have as yet no evidence that present biological methods will eliminate pathogenic organisms.

(3). Sewage may be simply discharged on to the surface of the earth and allowed to decompose, but unless the quantity be very small, and the place of deposit sufficiently far from human habitations and surface water-supplies, the practice is open to grave objections, especially in tropical climates under monsoon conditions, and measures should be taken to cover up the sewage with earth.

Again, the very prevalent practice adopted by Indian municipalities of burying excreta in deep pits is a modification of the old cesspool. Oxygen fails to get access to the mass, and we get a minimum of the desirable nitrification, with a maximum of slow putrefaction. The method is unscientific; it is slow and wasteful, always objectionable, and often dangerous.

"Trenching" stands in a different category, and provided it is carefully and properly carried out, it offers every advantage from the practical and scientific standpoints. It is indeed Nature's method in its simplest and most direct form; where land is available, of suitably porous character, well drained but with sufficient moisture; where the sewage is buried superficially and in moderate quantity, within the range of the nitrifying organisms and the access of oxygen, and where subsequent cultivation is not delayed, we have perhaps the most simple, scientific and adequate means of disposal for small isolated communities, where labour and land are cheap. One factor of prime importance is adequate and intelligent supervision; where "trenching" has failed in India and led to the employment of incinerators, it has been due to neglect or absence of one or more of the above conditions.

Coming now to the consideration of the various methods of disposal, it is obvious that the local conditions of each community must be taken fully into account. The conditions in India itself vary greatly, and as markedly from those which obtain in England, so that it is evident that a scheme which may be eminently suitable for one place is not necessarily desirable for, even if practicable in, another.

In England labour is very dear, land is valuable and the population is congested, and an organic system of water-supply and sewerage is very general; the problem to be faced, therefore, is the safe and expeditious disposal of a large quantity of fluid, comparatively lightly charged with organic impurities, without using much land in the neighbourhood of a town, and with a minimum of labour. The sewage of a large community, therefore, cannot be buried, and its discharge on to land has in most cases been accompanied by difficulties which have led to the introduction of the biological methods, which secure, at a minimum of cost, of labour and of land, an effluent that can be safely discharged into a river, under safeguards to water-supplies derived therefrom.

In India, on the other hand, the conditions affecting the majority of communities are very different—though water-supplies on European lines have been in some cases introduced, we have no complete organic system of sewerage as a direct adjunct to the water-supply, and we still live in the house privy and public latrine era. As a consequence of this and of the comparatively small quantity of water used for domestic purposes, the sewage will not bear comparison with that ordinarily dealt with in England, and it must be remembered that the daily average solid excreta of the native of India is from twice to thrice as large as that of a European. We have consequently to deal, in the main, with night-soil on the "dry" system; land is generally available, labour is cheap, microbial life is luxuriant, and there need be no question of an effluent. The best means of disposal therefore is, in the majority of cases, proper "trenching" on the lines, and under the conditions laid down; adequate supervision throughout, from the latrine to the disposal ground, being the great essential.

But we have seen how, in the cases of larger communities, other systems have had to be introduced, and the question has arisen as to how far the new biological methods may be adapted to Indian conditions, where circumstances prevent a direct application of sewage to

the land. Beginning tentatively, and dealing only with the domestic sullage water (including some urine) of individual dwellings, the Sanitary Commissioner with the Government of Madras, as early as 1895, devised a simple "filter" of ordinary porous material (gravel and sand), to be placed at the house-drain outlet, and which, in its most effective form, provided for the upward and downward passage of the sullage. Further, larger "bacteria beds" of similar material, but allowing only of intermittent downward filtration, were instituted by the same officer for the purification of larger quantities of the same "slop-water," where otherwise it would discharge into natural "tanks" or excavations near the inhabited site. It may briefly be said that these simple devices have amply fulfilled all expectations, and pending the introduction of arrangements for complete sewerage, they undoubtedly offer a scientific, safe and cheap solution of the problem of sullage disposal, which is indeed one of grave concern to all Indian sanitary authorities.

The first attempt to deal with the solid and liquid excreta on this system was made in Quetta in 1898, the apparatus being of a small experimental kind, on the lines of Mr. Cameron's Exeter process. The aim of Major Melville, R.A.M.C., who instituted and carried out this experiment, was to see what could be done with cantonment sewage diluted with equal parts of "slop-water," and subsequently with ten parts of water.

Owing to the short time at his disposal, this pioneer experiment was only carried on for three months, and no elaborate chemical analyses could be made; but the results were sufficiently encouraging as to make it plain that a very powerful addition had been made to our resources as regards the sanitation of cantonments, where owing to the nature of the soil, etc., the old system of earth-burial had fallen in disrepute, mainly as a probable factor in the prevalence of endemic typhoid fever.

Subsequently similar experiments on a larger scale were carried on in the Presidency Jail, Calcutta, and in Poona, in both instances on the lines of the Septic tank system; but the sewage treated in the case of Poona was considerably more dilute, the excreta of each person being mixed with 15 gallons of water. Here again the results have realised all anticipations, but the chief point of interest beyond the disposal of the excreta is the extraordinary manurial value of the effluent. Simultaneous cropping experiments were made on several small areas of land, to which poudrette, crude sewage, farmyard manure and effluent respectively were applied, the result being most markedly in favour of the last; it is confidently anticipated that a very large recuperative revenue will accrue on this account.

Lastly, it may be well to refer to some recent experiences gained in experiments carried out at Simla, since, owing to the strength of the sewage treated, the results attained have, like those of Quetta, considerable importance, with special reference to conditions peculiar to Indian communities, *e.g.*, cantonments, and to places where, although there be no organic water-sewerage system, smaller quantities of water are available, as from a stream or from light sullage.

The sewage treated was the crude night-soil (solid excreta with a varying amount of urine) together with the small quantity of ablution water each native uses, probably a pint on the average. Repeated experiments with "control" sewages artificially prepared showed that this consisted of from 8 to 10 ozs. of solids, from 15 to 20 ozs. of urine (for more than half the urine never finds its way to the depots), a varying amount of raw vegetable refuse, and some rubbish, rags, etc. The population is one in which the proportion of adults to children is very large, 6 or 7 to 1. To each night-soil unit with its pint or so of ablution water, five gallons of water were added from a stream which receives a certain quantity of the sullage drainage of the town, and in this way 500 gallons of sewage were daily prepared containing the excreta of 90 persons. It will be seen that, so far as the solid excreta are concerned, this dilution, as compared with an average of 3 ozs. per head for a European population, was only equal to something less than two gallons per head. Three small experimental installations were prepared; one on the Exeter plan, with a Septic tank of a capacity of 200 gallons, through which 100 gallons of the sewage were passed daily; the attached filter had a capacity when filled with "clinker" of 100 gallons. The second was a copy of the Dibdin double downward bacteria beds, 4½ feet deep, each having a capacity for 200 gallons of sewage, when filled with clinker of walnut size. The remaining 200 gallons of sewage were passed into a Scott-Moncrieff upward filtration tank or bed, and thence down through an aerating bed, which also accommodated the 200 gallons when plenished with finer clinker, 4½ feet in depth. These installations were worked daily save on occasional Sundays, for three months, the filters receiving but one charge a day; and for the greater part of the time the sewage was retained in them for periods varying from one to three hours; latterly it was allowed to flow through without retention.

Excluding the coarse adventitious rubbish which was screened off, the composition of this sewage was on the average of 10 analyses (controlled by analyses of artificially made sewage of the composition previously noted) as follows :—

	Grains per gallon.	
1. Total solids	304	Varying with the food grains ; large quantity of undigested grain and vegetable matter.
Solids in suspension	172	
Solids in solution	132	

	Parts per 100,000.
2. Ammonia (free)	14 to 16
3. Ammonia (albuminoid)	8 „ 10
4. Chlorine	16 „ 20

The chief points to be noted are the excess of suspended over dissolved solids, and the very large amount of albuminoid ammonia, due probably to the undigested grain and vegetable matters, and also to the relatively small amount of urine.*

It soon became apparent that the Dibdin beds could never work satisfactorily for more than a few days without requiring the removal of the felt of suspended solids which formed upon the surface and choked the pores of even the coarse material used ; but given that attention, the effluent from the lower bed was undoubtedly the best obtained, as might be expected, but the object of getting rid of the sludge was defeated. In this respect much more was hoped from the other installations, both of which call into play the so-called " septic " or putrefactive action of anaerobic organisms. This question has been so fully discussed of late that it need scarcely be entered on here, but the Simla experiments indicate that it is especially in very heavy domestic sewages that this stage of the " biological " methods offers the most advantages, and this was the most striking lesson afforded by the experiments. First, in this respect, the 300 to 350 grains per gallon entering the tank were invariably reduced to from 60 to 70 grains, of which only 5 to 10 grains were in suspension ; the result was identical from the passage through the upward Scott-Moncrieff bed. It should be noted that, whereas the sewage took two days to pass completely through the Septic tank, the full capacity of the Scott-Moncrieff bed was charged daily. At the conclusion of the experiment no deposit of sludge was found in the upward filtration bed, save a small layer half an inch thick, due to the last day's operations. The same may be said of the Septic tank, size $6' \times 2\frac{1}{2}' \times 2'$; the whole floor was covered with a layer of gritty sludge half an inch thick, while just below, in the inlet pipe, there was a small conical heap of $2\frac{1}{2}$ inches. Measurements had been taken at two spots in the tank every week, and at first there was a gradual increase in the deposit, which went on in a decreasing ratio for six weeks, and amounted at the most to $4\frac{1}{2}$ to 6 inches ; thereafter it steadily declined to the insignificant amount above noted. This settled satisfactorily one point of extreme importance in view of the nature of the sewage, and it only remains in this brief note to refer to the quality of the effluent.

A comparative tabular statement will best convey the facts of the means of the several analyses :—

	1	2	3	4	5
	Night-soil with 5 gallons of water per head.	Effluent from Septic tank.	Effluent from upward filtration bed.	Filtrate from aerating bed of Septic tank.	Filtrate from aerating bed of Scott-Moncrieff (upward) installation (No. 3).
		Parts per 100,000.			
1. Total dry solid residue	432	107	93	86	86
Solids in suspension	244	14	7	3	2
Solids in solution	188	93	86	83	84
2. Ammonia (free)	14·5	8·1	8·15	3·9	4·3
3. Ammonia (albuminoid)	9·3	2·8	1·9	1·08	0·9
4. Nitrates	—	—	—	1·1	1·42

N.B.—The chlorine was regularly present at 16 to 20.

* Fresh acid urine will give a total solid residue of roughly 2 oz. in 40 oz. of the fluid. A state alkaline urine yields little more than half this amount of solids.

It has to be noted that, although the "purification" attained may not be ranked as first class on some arbitrary standard, it is the result of contact with only one aerating bed, and all recent experiments have shown that almost any degree of purification may be attained by double or "multiple contact." But before finally appraising the affluent, one point of great interest remains to be noted. It is intended to discharge the final effluent into a rocky mountain stream, which has hitherto received the crude sewage to its great detriment. It seemed advisable, therefore, to enquire into the effect of mixing the above filtrate with the stream water, as it is obvious that a filtrate crowded with nitrifying organisms carries with it the means of self-purification if oxygen be supplied, as would certainly be the case in such a stream. Equal parts of filtrate and the river water were therefore mixed, and although analysis was carried out at once, the mean result of four analyses was as follows :—

	Parts per 100,000.
Ammonia (free)	0·93
Ammonia (albuminoid)	0·35
Nitrates	0·925
Chlorine	11·0

As the stream at its lowest yield will always provide a dilution of 6 or 7 parts to 1 of filtrate, there does not appear to be much left to desire on the chemical side of the question.

Without any pretention to a conclusive value, this note of a recent preliminary trial may serve to indicate a possible scope for biological methods under certain conditions in India.

Leprosy.—The volume* devoted to the report of the German Plague Commission contains a paper on Leprosy by Professor Sticker, of Giessen, of more than ordinary interest and importance.

Professor Sticker, who was one of the Commission, spent such leisure as he could snatch from his work in connection with plague in examining the lepers in the Matunga Asylum in Bombay; he also visited Nasik, where he examined 40 lepers, and, on his journey to Europe, he examined a few in Cairo and Alexandria.

The result of Professor Sticker's work is to show that the nose is peculiarly the seat of leprosy. It is in the nose that the disease begins; it is from the nose that it is spread; and it is in the nasal secretion of the sufferer that the bacillus of leprosy is to be found, if it is to be found anywhere.

Particulars are given of 153 cases, of which 57 were nodular, 68 were anæsthetic, and 28 were mixed. The bacilli of leprosy were found in the nasal secretion in 55 of the cases of nodular leprosy, the two exceptions being elderly women, in whom the disease had remained quiescent for some time. In the cases of mixed leprosy the bacilli were present in the nasal secretion in about the same proportion, 27 out of 28. In the anæsthetic variety of the disease the presence of the bacillus in the secretion of the nose was not so constant; in 23 out of 68 cases it was not found, but in 19 of these 23 cases the disease had made no progress for years. Moreover, it is probable that further examination would have reduced the number of negative results, for on several occasions the bacilli, although not found at the first examination, were discovered in abundance at the second. In almost every case, whether nodular or anæsthetic, young or old, recently acquired or apparently healed, some stage of ulceration of the nasal mucous membrane was to be found, generally over the cartilaginous portion of the septum.

Professor Sticker's experience leads to the following eight conclusions :—

1. The lesion in the nose, which generally contains and discharges large numbers of bacilli, is the single constant change in all cases of leprosy, in every form and stage of the disease.

2. The affection in the nose having the character of an ulcer or its sequel, although no trace of leprosy can be found elsewhere, must be something peculiar.

3. In every case of anæsthetic leprosy, whether it appears to begin on the hands, on the face, or on the feet, the leprotic lesion is virulent on the nasal mucous membrane as regularly as in cases of nodular leprosy.

4. So long as the leprosy is not completely healed, the nasal ulceration contains the bacilli in greater or smaller numbers. But even in cases apparently completely cured the nasal ulceration may remain virulent for years.

5. As a rule, relapses and extensions of the disease are heralded by local signs in the nose, particularly epistaxis.

* Arbeiten a. d. Kaiserlichen Gesundheitsamte, Vol. XVI.

6. The nodules of leprosy generally first appear in the immediate neighbourhood of the nose.

7. Signs referable to the nose, itching, severe epistaxis, catarrhs, swellings, etc., are described by many lepers as forerunners of their attack ; and such have long been known by the best observers as prodromata, although hitherto they have been erroneously explained.

8. The nasal ulcer containing bacilli may be found as the sole, and therefore the first sign of leprosy in children.

Professor Sticker gives the results of the examination of the nose in the 153 cases in the form of a table, which is reproduced below :—

		Cases in which the nasal mucous membrane appeared healthy.	Dry inflammation to ulceration.	Superficial atrophy of the mucous membrane.	Swelling of the mucous membrane with or without catarrh.	Contraction of the nasal passages.	Ozæna.	Advanced destruction of the frame of the nose.	Perforation of the Septum.
Nodular Leprosy	57 cases								
Cases with bacilli in nasal secretion	55 „	2 (12)	18 (8-45)	1 (11)	—	13 (8-50)	6 (12-60)	15 (10-60)	10 (10-55)
Cases without bacilli	2 „	1 (60)	1 (45)	—	—	—	—	—	—
Anæsthetic Leprosy	68 cases								
Cases with bacilli	45 „	6 (5-45)	10 (10-60)	1 (55)	2 (8-10)	5 (20-45)	5 (20-50)	16 (15-66)	11 (15-66)
Cases without bacilli	23 „	8 (12-60)	1 (45)	4 (40-66)	—	1 (60)	1 (45)	8 (45-50)	2 (50)
Mixed Leprosy	28 cases								
Cases with bacilli	27 „	1 (5)	4 (10-52)	—	4 (14-36)	3 (23-45)	3 (20-50)	12 (14-65)	11 (14-45)
Cases without bacilli	1 „	—	—	—	1 (12)	—	—	—	—
Total of all cases ...		18	34	6	7	22	15	51	34

The figures in brackets give the approximate limits of the ages of the lepers.

The practical conclusions are that in every case where leprosy is or may be suspected, the secretion of the nasal mucous membrane should be carefully examined for the bacilli of the disease.

Severe nasal catarrh, commencing ozæna, and, above all, frequent bleeding of the nose, occurring among persons who have lived long among lepers are suspicious, and require careful bacteriological examination and timely local treatment.

Doubtful cases of leprosy may be cleared up by discovery of the bacillus in the nasal mucous membrane.

A leper in whom the skin and nervous lesions have long ceased to progress can be regarded as free from danger to his surroundings, only when the complete healing of the primary affection in the nose is established by examination.

Therapeutic measures should be directed to the destruction of the disease in the nose, since experience teaches that all secondary manifestations tend to spontaneous cure, while the nasal affection is extremely persistent.

Tuberculosis.—At the International Congress on Tuberculosis, held at Berlin on May 24th to 27th, 1899, Lieutenant-Colonel A. Crombie, M.D., Indian Medical Service (retired), was the delegate appointed to represent the Government of India. This officer has furnished a most interesting report on the proceedings, with special reference to the prevalence and prevention of the disease in India, and it has been included as an appendix* to this section.

* Not reprinted.

ABSTRACT OF THE REPORT OF THE SANITARY COMMISSIONER FOR MADRAS FOR 1900.

(*Lieutenant-Colonel W. G. King, C.I.E.*)

General Population.

The population of the Madras Presidency, according to the last census, was, inclusive of Europeans and Eurasians, 35,641,828. The estimated population for 1898 is 37,715,417. The census population for which returns of vital registration were received, amounted to 33,288,122, or 93·4 per cent. of the total. Emigration and immigration statistics show that the Presidency lost 68,247, against 92,118 in the previous year, which was one of scarcity, and consequently favoured emigration. Of this number, about 98 per cent. was contributed by the districts of Ganjám, Vizagapatam, Gódávari, Madras, Tanjore, Madura and Tinnevelly. The migrations were chiefly to the ports of Burma, Ceylon and the Straits Settlements. The "natural increase" of the population under registration amounted to 212,774. Compared with the previous year, the population brought under registration shows an increase of 649,879. This has been effected in the districts of Madura, Ganjám, and Vizagapatam.

No change has been made in the system of registration. This was fully described in the report for 1893, and need not be here repeated. It is unlikely, until the Village Proprietary Act comes into force, that any great improvement can be effected in registration in rural areas. As illustrating the influence which is exercised by districts where zemindari tracts are large, it may be said that if the districts of Ganjám, Vizagapatam and Madura, where these predominate, be excluded from the calculation, it is found that instead of the total death-rate for the Presidency (as subsequently shown) being 21·0 it becomes 21·5 per 1,000, and the birth-rate, instead of 27·4, becomes 28·2 per 1,000.

Births in Districts.—A total of 911,742 births was registered during the year, affording a birth-rate of 27·4 per 1,000 upon the census, and 24·3 upon the estimated population. This represents a decline of 1·1 per 1,000, in the birth-rate when compared with the five years' average, implying a loss to the population of 36,573 souls. On looking at the figures for the various districts, it will be recognised that this decline has not been brought about by a single factor. There is no system of registration of marriages in this country—although were one introduced it might well yield an income that would go largely towards the development of a vital statistics department; but, there is reason to presume that marriages have been deferred during the last three years, as far as feasible; that is to say, as far as the caste customs directing marriage of a female within a certain age will allow, because evil times have been prophesied. Again, the decline in the birth-rate that was alluded to at page 32 of the last year's report as having already exhibited itself in the districts affected with famine* (1896-97) necessarily was more pronounced in 1898.

But, in the case of Madura, which shows a decline in the birth-rate, and claims, moreover, the highly satisfactory figure of 15·6 per 1,000 for its death-rate (notwithstanding the presence of cholera throughout the year in the midst of the population) I consider the main cause is defective registration. It is presumed this has chiefly occurred within the zemindari areas. The heavy fall in the birth-rate in South Canara cannot be so accounted for, and its seems probable, therefore, that this district approached a critical condition owing to the high price of food-grains during a portion of 1896-97. It will be remembered that the districts of Bellary, Kurnool, Cuddapah, Vizagapatam, and Ganjám were recognized officially as affected with famine. Of the total decrease in the births, 63·0 per cent. is due to these districts. Parts of the districts of Malabar, Chingleput, North and South Arcot were also recognised, during the continuance of high prices, as approaching a condition where public help would have been necessary. These districts contribute 33·1 per cent. of the total decrease. On the other hand, increase of the birth-rate over the average occurred in districts where the chief

* The Ceded Districts alone were considered.

characteristic is the large extent of country under irrigation, affording the agricultural coolie a fair amount of certain labour. Thus the districts of Trichinopoly, Gódávari, Kistna, Tinnevelly and Tanjore yielded 20,149 more births than warranted by the average for the previous five years. Births of boys to girls were in the proportion of 104·3 to 100 girls, against 103·9 and 100 of the previous year. The birth-rate according to classes was :—Native Christians 22·9, Muhammadans 23·5, and Hindus 27·8. In the previous year, the rates were 23·7, 25·4, and 22·3, respectively.

Births in Municipalities.—The total birth-rate in municipalities was 34·9 per 1,000, against 34·4 of the previous year, and against 27·4 for the total Presidency for 1898. Notwithstanding that, of a total of 59 municipalities, 25 exhibit a decrease below the average of the previous five years in the aggregate, there has been a gain in the birth-rate of 0·5. The gradual increase of the recorded rate (not be it remembered the true rate according to either the census of Stokes or Stuart) due to the influence of better registration and of increasing increments of population, is shown in the following table :—

Years.	Birth-rate per 1,000 of population.	Years.	Birth-rate per 1,000 of population.
1892	31·4	1896	36·1
1893	34·1	1897	34·4
1894	33·2	1898	34.9
1895	35·3		

Deaths in Districts.—699,108 deaths were registered, giving a total death-rate on the census population of 21·0, and, on the estimated population, of 18·6 per 1,000. This is a decrease of 4·4, when compared with the previous year. This is accounted for chiefly under cholera, fever, and dysentery and diarrhœa. The distribution of death causation is given in the following table, which also enables a comparison to be made with the previous years :—

Years.	Birth-rate per 1,000 of population.	Death-rate per 1,000 of population.						
		Cholera.	Small-pox.	Fevers.	Dysentery and Diarrhœa.	Injuries.	All other causes.	Total.
1892	25·1	2·3	1·3	8·3	1·9	0·3	9·0	22·3
1893	27·0	1·0	0·8	7·7	0·7	0·3	8·8	19·3
1894	27·7	1·3	0·3	8·0	0·7	0·4	9·3	20·0
1895	29·1	0·6	0·1	8·3	0·7	0·3	9·6	19·6
1896	29·9	1·5	0·3	8·0	0·7	0·3	9·8	20·6
1897	28·7	4·4	0·7	9·0	1·2	0·3	9·8	25·4
1898	27·4	2·0	0·6	7·5	0·9	0·3	9·7	21·0

When compared with the previous year, the districts of Chingleput, Kistna, Nellore, Nilgiris, Salem, South Arcot, and Trichinopoly showed an increase in the total death-rate.

The total death-rate in rural towns was 19·0 per 1,000, against 21·0 for the Presidency, and 31·9 for municipal towns. The infantile death-rate, per 1,000 of births, was 163·3—a rate of 1·2 per 1,000 less than the previous year, and 6·4 higher than in 1896. This result points to the influence of the higher price of food-grains on the obtaining of luxuries suitable for infant life during 1897-98, and the production of weakly infants by ill-nourished mothers.

Deaths in Municipalities.—The total death-rate in municipalities amounted to 31·9 per 1,000, against 33·3 for the previous year. There was a decrease of mortality in 39 towns. Sixteen towns showed an increase of over 1 per 1,000. In certain of these an increased mortality has been registered under the indefinite head of "all other causes." Thus, under this head in municipalities, during 1898, a greater proportion of deaths has

been registered than hitherto. This might be explained on the theory that, as education advances, it is becoming increasingly common to specify the real cause of death, as diagnosed by a qualified medical man, instead of confining statements to the simple heads given in the register ; but the increase (1·8 per 1,000) is of too sudden a nature for this theory to satisfactorily account for it. It is more probable that the "plague scare" has caused alteration in methods of registration elsewhere than in the City of Madras. Such an explanation does not, however, get rid of the fact that increased total mortality actually existed in certain instances, and the suspicion may naturally arise that, in, say, Tiruvannámalai—a pilgrim resort—in the absence of any registered increase of cholera and fever, the heavy rate of 12 per 1,000 above the previous year must be due to some new condition, for example, unreported plague. It is, however, a municipality that has been well drilled as to sanitary precautions in reference to festivals, and it may be taken for granted that the selection of "all other causes" for registration was induced by self-interest on the part of the inhabitants, whilst activity in registration in this but lately constituted municipality may really account for the greater part of the supposed total increase. The probable actual cause of increased total death-rate in the City of Madras (cholera falsely registered) is alluded to under "Fevers."

The infantile death-rate in districts and towns is noted below. It is held that the demand of factory life upon a large number of the female population of England, tells most adversley upon the infantile death-rate, owing to insufficient time available for females to attend to their infants. In 1898, the London decennial average infantile death-rate was 151, and for the 33 "great towns" in England the same average rate was 167. If these figures be contrasted with those exhibited below, it will be seen that the death-rate amongst infants in this country is appalling. As both rates are reckoned per 1,000 of births, they are strictly comparable—the error, if any, being most probably in the full mortality of Madras infants not being correctly exhibited ; that is to say, that births in this country are more likely to be registered than the deaths of infants. I have, in a former report, adverted to the cause of such heavy mortality, namely, the ignorance of the poorer classes of the most simple ideas of sanitation, in connection with child-life. There need be no question as to purposeful neglect. The mothers of the uneducated classes in this Presidency cannot be excelled in any nation as to devotion to their children. The advent of a female infant is certainly regarded as somewhat humbling to the pride of the head of the family, still she gets fair treatment so long as, at reasonable prices, food is obtainable ; when grain becomes dear, it is possible that the male child would receive the greater share of attention. The gradual rise of wages will ameliorate conditions following the high price of grain in time. The matter of ignorance of mothers can only be altered by better attention to spread of general education and of sanitary knowledge amongst them.* It will, however, be noticed if Madras be placed in its proper place as a municipality, and be not regarded as a district, that the total district infantile death-rate becomes 160·6 per 1,000 of births, which is not much above that quoted for London, and is less than in the 33 "great towns." Probably, an infant's death in a rural area is less likely to be registered than that in a municipal town ; but, allowing for this fact, the rates are so enormously to the disadvantage of the latter that they cannot but be regarded as the expression of the insanitary conditions incident to the inhabiting of sites crowded with dwellings, inefficiently protected by the present type of municipal efforts towards rubbish and night-soil removal, unprovided with sewerage systems, and frequently possessing water-supplies innocent of the most simple modes of protection.

If it be granted that to a number of towns this description be correctly applied, the question as to which shall exhibit the heaivest infantile death-rate, would ultimately be determined by the relative capability of the soil to dispose of sewage reaching it, in respect to its nature and configuration, and proximity of the sub-soil water ; all matters that possibly affect the *bacillus enteritidis sporogenes*, and other forms of microbic life having a relation to intestinal fluxes. Bellary may well be regarded as a town whose sub-soil is saturated with sewage ; its rate is 324·9 per 1,000 ; the same may be said of Negapatam ; its rate is 276·2 ; and of Madras, with its 297·7 per 1,000, the same is true. In the case of Ootacamund (304·5) not only has the soil saturated with sewage in the neighbourhood of the native dwellings to be thought of, but the rigour of its climate. It is noteworthy that in Coonoor, the major portion of which is drained, but where the climate factor is also to be contended against, the rate is 190·5 per 1,000.

---

* The desirability of efforts for spread of sanitary knowledge amongst women is, I am glad to say, engaging the attention of several native gentlemen, notably, C. V. Swaminatha Aiyar, editor of the *Viveka Chintamani*.

Chief Diseases.

Cholera.—A total of 65,444 deaths occurred from cholera, yielding a rate of 2 per 1,000 of the population of the Presidency, against 4·4 per 1,000 in 1897, and a decennial average of 2·1 per 1,000. The incidence of the disease was very heavy in Tanjore (6·7), Trichinopoly (5·5), South Arcot (5·2), and Kistna (2·9). These are the great irrigation centres of the Presidency, and offer good facilities for the transmission of the cholera microbe from village to village by means of lengthy channels that are liable to contamination by reason of the insanitary habits of the people. The only district where irrigation under this plan is not carried out largely that was much affected was Nellore, where the death-rate from this cause was 2·8 per 1,000. This was the district affected with famine during the year. Granting that no cases of "famine diarrhœa" were included in the returns as cholera, the various conditions incident to scarcity indubitably predispose the individual to attack, and to spread of the disease in the community concerned.

The measures taken to combat the disease in rural areas by the local authorities, in spite of reminders, cannot be described as adequate. Notwithstanding the training of a large number of Certificated Sanitary Inspectors available for special work in connection with epidemics, Local Fund bodies cannot readily be prevailed upon to undertake systematic measures with the aid of these men. Matters are, however, very much better than a few years back, when the chief idea of certain Local Fund bodies in dealing with cholera was to distribute "cholera pills," by means of vaccinators. Hospital Assistants are detatched, if somewhat tardily, for this duty, and attempt to combat conditions (for which they are not specially fitted as in the case of Certificated Sanitary Inspectors), more especially with reference to specific contamination of the water-supplies of villages. These bodies, however, almost invariably fail to support their efforts by supplying menial staffs necessary to ensure correct sanitary results.

The rules for combating cholera in municipalities laid down in G.O., No. 1,536 M., dated 9th September, 1896, continued in force. As remarked in last year's report, their utility is greatly minimised by the power left in the hands of the Collector to approve of any smaller staff being employed than that laid down in the rules as the minimum. Although the Order provides definitely for the provision of sufficient funds for effecting the scheme, the first thoughts of Chairmen of Municipalities seem to be how cheaply the system can be nominally effected, and, apparently on the ground of economy, this is a policy that is not actively disapproved by the collectors. The Government Order also places in the hands of the collector the most important task of giving the warning to the municipality, as to when it is necessary to put in force the rule requiring the employment of a staff for observation. No instance has yet come to the notice of this office of collectors having given warning to municipalities *at this stage*. Consequently, the system which contemplated a method of observation, which should secure rapid action, on the introduction of the first case of the disease, has degenerated into a method of prevention of spread, *after the disease has exhibited itself*. The effecting of sanitary measures against epidemic disease demands at the hands of the local bodies responsible a rigid adherence to certain principles and methods; relaxation of these, at the option of this or that official, condemns their original necessity, and permits of flaws that stultify them.

In the municipal towns of Palni, Nellore, Chidambaram, Mannárgudi, and Trichinopoly, the disease was severe. Of these, Trichinopoly is the only town in which the rules above referred to are in force.

On making a comparison of the total population under the rules and those not, the incidence of the disease is found to be as follows:—

	Incidence of cholera in			
	1895.	1896.	1897.	1898.
Populations under the Cholera Rules in 24 towns=987,835.	0·7	2·3	5·3	2·2
Populations *not* under the Cholera Rules in 21 towns=428,914.	0·8	3·3	7·6	1·8

Had the populations under the rules been attacked at the same rate as those not subject to them, they would have lost, during 1895 to 1898, 2,964 more lives than they actually did.

Small-pox.—There occurred 20,490 deaths from small-pox. This represents a rate of 0·6 per 1,000 upon the census population. Within the last three years there has been a steady improvement in the rates within municipal towns as compared with their surrounding rural areas. This is possibly *inter alia* due to the influence of G.O. No. 1502 M., dated 19th October, 1894, which demands that the Chairman shall give a complete account of the methods of disposal of all births that have been registered, and have arrived at an age to receive vaccination.

The frightful rate of 12·2 per 1,000 registered against Ganjám, during 1897, has undergone a decline; though in 1898 the mortality from this cause (8·5 per 1,000) was still of a most serious nature, It will be remembered that the impetus given to the disease during 1897 was due to famine conditions, leading to the crowding of the people upon works. What with the existence of extensive hill tracts inhabited by a class of people who probably would much prefer inoculation t o vaccination, and the impossibility of dealing satisfactorily with any sanitary subject in zemindari tracts, Ganjám presents a most unpromising field to the sanitarian. Indeed, so little has it been considered possible to deal with this district by ordinary methods, that for the last ten years, in the hill tracts, the entire responsibility for administration of the Vaccination Department has been in the hands of the civil authorities,

In judging of the magnitude of small-pox epidemics, it is well to hold in mind that under our present system of registration in rural areas, and to a less extent in municipal towns, deaths from measles are apt to be included under "small-pox."

Fevers.—It is a trite statement, but one necessary to be held in mind that, under the head of "fevers," the majority of all affections in which pyrexia is a prominent symptoms are likely to appear, as a sequence of the present system of registration and state of medical advane of the country. Nevertheless, it is safe to assume that the greater number of deaths so registered are due to malaria. In the year under review, there were 248,638 deaths, from fevers, which represent 35·6 per cent. of the total mortality reported, and a death-rate from this special cause of 7·5 per 1,000 of the population, against 9·0 of the previous year. The decrease was chiefly marked in districts that in 1897 had been affected with famine; but, in Anantapur, it is trivial. From this may be argued better nutrition and better resisting power to malaria of the people of these districts. A marked exception to the general decrease is exhibited in the case of the Nilgiris, where the death-rate of 22·1 per 1,000 from this cause was registered, against 17 per 1,000 in 1897. This was accompanied by a fall in the birth-rate. If this does not represent mere vagaries in registration, the only feasible explanation, in default of special investigation, is the departure from the rainfall conditions of 1896, representing a gradual decline and, consequently, a changed line of saturation of the sub-soil influencing the production of the malaria germ; thus, in 1896, the total rainfall was 85·47 inches, in 1897, 76·75 inches, in 1898, 70·32 inches.

It is probable that the death-rate from fever in Madras town does not represent the truth. During the prevalence of cholera, there was an increased registration of deaths under "fever." A joint investigation by the Health Officer and myself, satisfactorily proved that the apparent increase had been brought about by false registration of cholera under that head. Subsequent to October, however, a decline in fever below what might normally be expected, during the last quarter of the year, occurred. This result has been stated by the President of the Municipality, to be due to people reporting an abnormal number of cases under "other causes." "Dysentery and diarrhœa" had become an unsafe head under which to register, as it was likely to be followed by enquiry as to cholera. On the occurence of plague in the Mysore territory, and increased vigilance of the sanitary staff as to "fevers," it became unsafe to register under this head, lest enquiry should be made as to plague. Hence, the refuge for false registration under the convenient head of "other causes," has been fully utilized. The following statement illustrates these facts, and affords a curious illustration of the difficulties the sanitarian in this country encounters,

in attempting to interpret registration results, in reference to the health state of populations :—

——	Years.	July.	August.	September.	October.	November.	December.
Cholera	1897	0·3	1·1	1·0	"Plague scare."		
	1898	2·3	7·6	4·3			
Fevers...	1897	10·8	13·2	11·5			
	1898	15·0	19·8	16·0			
Fevers...	1897	Cholera prevalent.			12·9	10·5	9·8
	1898				5·3	3·7	2·5
All other causes	1897				17·7	17·2	18·6
	1898				25·9	25·2	26·8

The death-rate from fever in municipalities was 7·5 per 1,000, the same rate as in districts as a whole, that is, including municipalities, The highest rates were registered in Cuddapah (14·8), Kurnool (12·5), Madras (12·4), Ootacamund (11·8), and Vizianagaram (11·7). I have already shown, in former reports, that the variation in the fever rate in Madras town follows closely the fluctuations of the sub-soil water. In my inspection notes of 1894 on the town of Madras, I showed that the "period of greatest mortality is that which immediately follows the greatest fall of the subsoil water level, and heralds a commencing rise." In my report on the same subject, embodied in G.O., No. 672, Public, dated 28th May, 1897, I also pointed out that the incidence of fever, diarrhœa, dysentery, and cholera, is influenced by sub-soil water fluctuation, more especially during the stage of depression. This term "fluctuation," I may state, was used in reference to variation from a known normal period regarded as a standard. I also pointed out that, for the time being, the town exhibited during the continuance of a high sub-soil water level greater freedom from fever ; this qualification being with reference to the fact that a fall subsequent to a great rise—a heavy fluctuation—would be followed by increased mortality. These statements from records maintained in this office seem justified. In the absence of any other observations, the levels hitherto trusted to have been those supplied by the Military Works Department in respect to the Seven Wells water-works. These, however, cannot be regarded as fully satisfactory. Systematic observation in suitable localities throughout Madras would seem most desirable. I specially draw attention to this, as the data at my disposal show that since the North-East monsoon of 1896, there has been a tendency for an abnormal rise of the subsoil water. There has also been of late years an increased consumption of Red-hills water in the but partly drained city, as shown by the following statement, that must at least add to soil moisture :—

	C. ft.
1896	436,953,834
1897	476,215,173
1898	488,625,534

There are reasons with reference to the diminishing use of the Seven Wells Water, why the supposed rise of the sub-soil water may be less than supposed ; but the chances are that a fluctuation of this nature has occurred. In this connection, the fact is worth remembering in regard to future prospects as to plague.

In Cuddapah also the incidence of fever prevalence is, within certain limits, affected by the rainfall, and, it may therefore be safely argued, by fluctuations of the sub-soil water, as will be seen from the following statement :—

Official years.	Total rainfall in inches.	Death-rate from fevers.	Official years.	Total rainfall in inches.	Death-rate from fevers.
1890–91	32·15	19·3	1895–96	33·02	14·9
1891–92	15·40	14·1	1896–97	20·57	19·2
1892–93	44·68	22·2	1897–98	31·11	13·2
1893–94	38·97	29·6	1898–99	*27·85	*14·7
1894–95	34·86	16·9			

* Obtained from the statistics of first nine months of 1898–97.

Dysentery and Diarrhœa.—The rate for deaths from "dysentery and diarrhœa" fell from 1·2 of the previous year to 0·9 per 1,000 of the population. This less frequency of bowel affections may fairly be regarded as due to improved dietary of the people, following the fall in the price of grain. The decrease occurred in all districts except Madras, Chingleput, Nellore, Salem, and South Arcot. The greatest mortality occurred in the months of January, November, and December. I have already referred to the condition of the soil as influencing infantile mortality—usually by inducing catarrh affections of the intestine. The intimate relation of soil and water, however, further forces itself upon notice in considering the mortality at other ages. It is, of course, possible to have a town situated on sewage sodden soil supplied with pure water, should it be brought from beyond the contaminated area ; but, it may happen, that a pure derived water from the outside, may, under several circumstances, be defiled by the sewage-laden soil. It is, in short, difficult to escape the penalty of the close connection between the soil and water. Thus, there heads the list of mortality from diarrhœa and dysentery within within municipal towns, Tuticorn, which yields a rate of 9·3 per 1,000. In this town, water is received from a tank 4 miles distant. It is open to contamination on its way to the town, but probably to nothing like the extent it is on delivery within the town, as old and pervious pipes are employed emptying into pervious cisterns forming dip-wells. The sub-soil passed through contains much brackish water, and the filtered sewage of the town —which has no sewerage system. The Sanitary Board has recently, against my advice, approved of a scheme for improvement of the water-supply on the principle of protecting it during its transport to the town, but neglecting its protection when passing through the sub-soil in the pervious conduits referred to, and when exposed in the open wells. It will be of advantage to note the result upon the "dysentery and diarrhœa" rate, in future years, of this halting policy. In Cochin, which has the next highest rate (7·5), the water obtainable is brackish and presumably, sewage tainted—considering the nature of the surroundings. Such fairly pure water as is obtainable, is procured at great expense by boat from a distance of 12 miles. The prevalence of filariasis to an extent to cause the name of "Cochin leg" to be synonymous with elephantiasis, sufficiently bespeaks the fact that the water of the locality is open to lodgment by the mosquito. The fact that Madras (7·5) possesses a public water supply, (albiet delivered unfiltered after passage through an unprotected channel) by no means implies that the people obtain the full possible sanitary benefit from it. There hardly exists a house in the thickly inhabited areas that does not have on its premises an open well, with pervious steining, two or three paces removed from the latrine. Of course, the plea is that such water—chemically little better than a sewage filtrate—is used solely for the washing of eating and cooking vessels ; but this statement does not absolve from the sanitary sin, nor its consequences. As for Coonoor with its rate of 6·3, it affords a lamentable example of a town being surrounded with pure water sources, but allowing such as it possesses to be grossly defiled by absence of protection.

Injuries.—Under "injuries," the practically invariable figure of 0·3 per 1,000 was registered. It is evident that neither the increase of railways nor of manufactories—the latter being in number still very small and under full operation of the Factory Act—has sufficed to cause any marked result on mortality.

All other causes.—Although, as remarked in discussing registration, there was an increased tendency in municipalities to register under this head, owing to "plague scare," the total was not sufficient to affect the supposed incidence in the population as a whole. The figure for 1898 (9·7) approximates closely that for 1897 (9·8).

Sanitary Works.

Municipalities.—It might have been thought, with plague threatening to invade the Presidency, that the improvement of the sanitation of municipal areas would have been carried on with unusual energy. In the matter of attempting to make the best effort with the means available, this is probably the case, but it is not possible to record any departure from the routine that would signify the introduction of new methods, or additions to those already in existence. The funds available in 1897–98 were "nursed" carefully by municipalities, because it was not till the success of the north-east monsoon was established that all fears of famine had departed ; during 1898, there existed the restraining influence of the knowledge that, should plague invade the Presidency,

there would be great difficulty in meeting the expenditure required for special measures to combat it.

46. The following statement shows the expenditure on sanitary improvements.

	1897–98.		Rate per cent. of expenditure to total allotment.	1898–99.		Rate per cent. of expenditure to total allotment.
	Amount sanctioned.	Amount expended.		Amount sanctioned.	Amount expend edduring the nine months ending December, 1898.	
	£	£		£	£	
For conservancy	43,155	41,863	97·0	47,340	33,212	70·2
For improvement of village or town sites.	18,929	16,382	86·5	15,950	10,136	64·0
For improvement of water supply, cleansing, repairing, and construction of tanks and wells.	65,062	33,241	51·0	31,140	8,021	26·0
For sanitary arrangements during fairs and festivals.	894	795	88·9	899	499	55·5
For construction and repair of markets and slaughter-houses.	2,645	1,571	59·4	1,303	550	42·2
For other sanitary outlay ...	7,993	7,186	89·9	8,138	3,911	48·0
Total	138,678	101,038	72·9	104,770	56,329	53·8

In my report for 1895, I drew attention to the advantage that would accrue to municipalities not provided with a sewerage system and not likely to be in a position to undertake a complete scheme, by introducing the Shone's system permanently for night-soil disposal by pail depôts and, subsequently, by gradual extension, for receipt of sewage from areas within a reasonable distance of these depôts. Since then, I have been in communication with Messrs. Ault & Sons, the patentees, who agree with me as to the practicability of the method. An estimate was framed for the town of Bellary showing that the total night-soil of a population of 59,467 could be discharged upon farms outside the town at an initial cost of about 1 shilling per head. This suggestion must not be confused with the use of the Shone's system for a complete sewerage scheme. The proposal looks solely to disposal of night-soil in a more cleanly and expeditious manner than at present by the cart system, whilst sewage can be added for section after section of the town as funds or inclination decide. Such a method, of course, ought not to be applied, when a complete scheme, intended to deal with night-soil as well as sullage water, can be afforded within a reasonable period. Its correct place would be the serving of towns which are in debt for water schemes, and are not likely to be able to find funds for complete sewerage during this generation.

In the sanitary history of municipalities, during the year, the "typhoid fever scare" at Ootacamund attracted some public attention. The cases were but few; the social position of the patients, however, induced considerable publicity. The fact that sporadic cases of typhoid fever are not unknown in Ootacamund, has been recognized for many years. This being so, I sought in my Inspection Notes in 1893 and in 1896, and, again, in discussions with the Collector, Chairman of the Municipality, and Sanitary Board, in 1896, to force upon notice those improvements connected with the protection of the water-supply, night-soil concervancy, milk supply, and clothes washing, which the existence of this special disease obviously demanded. In face, however of the good health of the station in those years, these warnings were regarded by some of the officials concerned as due to the theoretical tendencies of the votaries of sanitation. Nevertheless, Government took the matter into consideration, with the result that much data have been laboriously collected in regard to improvement of the water-supply, certain urgent defects as to the main sewer have been attended to, and a scheme for sewerage has been worked out. The lesson derived from the incident is that it is difficult for municipalities to comprehend that the function of the sanitarian is not solely to deal with epidemics that are existent, but to give timely warning of the defects that may bring them about. As stated under "Personal Proceedings," the investigation of the occurrence of typhoid fell to Major Thompson, I.M.S., who acted during my absence on leave. He submitted a

valuable report on the subject, which confirmed the sanitary pleadings of myself and my Deputy during the preceding years.

The income derived by municipalities by the sale of night-soil is gradually undergoing an increase, as the utility of this form of manure is better appreciated ; money realized by sales at the end of this decade has exceeded that at its opening by about £670. I regret that I can place on record no further advance as to sewage farming. It was practised in the following towns:—Madras, Erode, Tanjore, Anakápalle, and Vizagapatam. Tinnevelly purchased a plot of ground, but, beyond this, took no further step in the matter.

The question of improving the condition under which sewage farming shall be conducted at Tanjore, still engages the attention of the Sanitary Board.

Filtration of sewage is conducted at Vizianagram, Vizagapatam, Kumbakónam, Bezwada, Negapatam, and Rajahmundry, and on a small scale at Bellary. A Sanitary Inspector engaged on plague duty has also informed me that he successfully introduced this method in certain villages for disposal of sewage, where no regular system for removal existed. Sewage filteration (by means of "filter trenches") is recognized in the official regulations as the method to be adopted in the health camps, during plague operations.

In Madras City, night-soil and rubbish disposal continued under the usual unsatisfactory conditions. The incinerator, which will deal with part of the rubbish, was under construction. In Mylapore, an under-ground sewerage system was completed. I regret to say the principle of receiving sullage water, to the exclusion of night soil was adopted.

District Boards.

The Act for Local Fund areas is, I understand, in a state of revision that will shortly permit its appearance. If it embraces certain of the points I anticipate, it will bring about an enormous advance of sanitation in rural areas, and provide the requisite funds. At present, the necessity for husbanding funds for plague purposes, mentioned in reference to municipalities, was more marked in District Boards. The result was a fall off in the amounts allotted for sanitary purposes of a routine nature. The sums allowed by various districts differed within wide limits, the proportion of income allotted in certain of these being absolutely inadequate. The President of one of the Boards, which gave a contribution to which this term may be safely applied, has defended this position by pointing to some absurdities in the way of attempts at conservancy in villages ; but, with the same breath, allows that such results are due to want of supervision, ignoring the simple fact that did his Board allot sufficient funds supervision could be obtained. Per head of population served, the total expenditure by District Boards upon sanitation during 1897–98 amounted to only 3·1 pies or about one farthing at current exchange.

The following statement exhibits the expenditure on sanitation during the year:—

	1897–98.			1898–99.		
	Amount sanctioned	Amount expended.	Rate per cent. of expenditure to total allotment.	Amount santioned.	Amount expended during nine months ending December, 1898.	Rate per cent. of expenditure to total amount.
	£	£		£	£	
For conservancy	23,294	20,683	88·8	23,258	16,611	71·4
For improvement of village or town sites.	5,233	2,415	46·1	5,008	1,797	35·9
For improvement of water-supply, cleansing, repairing, and construction of tanks and wells.	10,095	7,812	77·4	8,814	3,703	42·0
For sanitary arrangements during fairs and festivals.	1,189	1,108	93·1	1,120	599	53·5
For construction and repair of markets and slaughter-houses.	4,364	2,888	66·2	3,530	1,275	36·1
For other sanitary objects	2,182	1,546	70·9	2,097	671	31·9
Total	46,357	36,452	78·6	43,827	24,656	56·2

It is a maxim in sanitation that epidemics do not come to populations as unmixed disasters. They force upon the authorities responsible, facts that much report making would not convince them of. Should, however, plague persist in this Presidency, before any advantage can take place, the chances are that routine sanitary improvements will be very materially decreased in number and value, owing to the demand for funds. Even the sanguine sanitarian finds at last that it is hopeless reporting to bodies that have no funds to bestow on the improvements he indicates. Not only is advance thus likely to be impeded in sanitary matters proper, but the prophylactic action of vaccination is likely to receive material check. As will be further explained in the Vaccination Report, the people (more especially of rural areas), have confused anti-plague inoculation with vaccination, with the result that a very heavy decrease in operations has occurred throughout the Presidency, The result must be, in the end, a greater loss of lives by small-pox than can have been saved by anti-plague inoculation. In short, the maxim will doubtless remain true: as an effect of the "plague scare" sanitation in the Presidency will advance, but *when* this will occur the future alone can show, and in the meantime, an approach to stagnation is the immediate result.

Personal Proceedings and General Remarks.

At the beginning of the year, the Government Order requiring me to devote my attention to plague and famine matters, instead of routine sanitation continued in force. Famine work terminated with attendance at the Famine Conference at Waltair, except that I carried out a tour near Panem and Dhone, Kurnool district, with the object of ascertaining the condition of agriculturists at the termination of famine operations. In February, at the request of the Inspector-General of Prisons, I was deputed by Government to report on the unhealthy condition of the Rajahmundry Jail. The prisoners seemed to me to be suffering from sub-acute beri-beri. The recommendations then made have, I understand, been acted upon with good results. During March, I proceeded to Tungabhadra and, in consultation with the Local Fund Engineer and Collector, advised as to the erection of a railway inspection plague camp. In consultation with Mr. Moss, the officer in charge of the Public Works Workshops, the supply of temporary steam disinfecting machines for present and future requirements of plague was arranged for, and their effectiveness was tested. In this month also, I inspected the railway inspection plague camp at Arkonam. References, at this period, from Government were of a frequency and nature that it was considered advisable by Government I should not undertake touring until further orders, especially as in the state of uncertainty as to future demands on the funds of Local Bodies, practically no good could result from a series of reports on the routine sanitary requirements of localities.

In the first week of June, I was granted privilege leave for a period of three months. During this time, Major Thompson, D.P.H. (Camb.), acted for me. Towards the end of June, the presence of tophoid fever in Ootacamund having excited public alarm, Major Thompson proceeded there, and rendered a full report for the information of Government. He was then directed to proceed to Hubli, with the object of examining methods for combating plague, and, at the same time, to ascertain how far suitable measures were being taken to guard the frontier stations of this Presidency. He, consequently, visited Hospet, Adóni, and Hubli. In August, plague having appeared at Guntakal, this officer was directed to proceed thither. He inspected the villages of Tiruvallam and Jungalpalli of North Arcot, where plague had been imported from the Mysore Province. He also selected the site for a plague camp at Jalarpet.

I resumed charge of the office from Major Thompson in the first week of September. I found Government had directed that a special inspection of Madras City should be conducted, in reference to an unexplainable increase of mortality under the head of "fever," which it was feared might imply that plague had become epidemic without its being recognized. In conjunction with the Health Officer of the Municipality (Lieutenant Cornwall, I.M.S.), I conducted a house-to-house inspection in various typical localities. This inspection occupied several days; its result is referred to under "Fevers." On the 14th September, I proceeded to the villages of Guntakal and Timmancherla in the Anantapur district, and Chippagiri in the Bellary district. In these, indigenous plague had appeared. This occupied up to the 25th of that month. During September, a Plague Commissioner, Mr. Hammick, I.C.S., was appointed by Government. The

position of this office with respect to the Plague Commissioner is thus defined, in the Government Order directing his appointment (G.O., No. 1122 P., dated 20th September, 1898):—"The Sanitary Commissioner and the officers in his Department shall give every possible assistance to the Plague Commissioner in the conduct of his duties, lending him their assistance and advice to the utmost of their power, and carrying out his orders."

In October, I was directed by Government to supply a scheme for the defence of the City of Madras against plague, in consultation with the President, and subsequently was desired by the Plague Commissioner to report on various sites intended for Municipal plague hospitals and camps, and caste hospitals. During this month, it being found, in respect to the *personnel* for the scheme for maintaining a system of observation in districts "imminently threatened" with plague, that the Certificated Sanitary Inspectors available were insufficient in numbers, with the sanction of Government, I trained and examined 59 men as Temporary Sanitary Inspectors, in referance to the legal and sanitary requirement and methods in respect to plague, and sufficiently as to general sanitation to enable them to grasp the main particulars as to conservancy, water-supply, and the hygiene of dwellings, etc. On November 10th, I returned to the plague-infected areas round Guntakal, and remained there till the 14th. On that date, at the special request of the Collector of South Arcot, I proceeded to Tiruvannámalai, with reference to preparations against importation of plague, at the important annual festival at that place. On the 25th November, I proceeded to inspect the railway inspection station at Hospet, and the frontier road stations in the district of Bellary, as the Bellary district seemed threatened by invasion from H.H. the Nizam's territory. I proceeded to Kopbal in the Nizam's territory, and ascertained the extent to which plague was prevalent. Kamalapur, Hosur, and Taliari ghat was inspected. The town of Bellary was carefully examined in reference to its preparations against plague, and the Municipal Council was met and conferred with. On the 1st December, I proceeded to Bangalore to give evidence before the Plague Commission. On the 16th December, I proceeded to Guntakal, and accompanied the Plague Commission during its inspection. By this time, Mr. Beckley, I.C.S., had been appointed Plague Commissioner; with him I inspected Maddikera, a village in the Kurnool district, where plague had appeared. From thence I proceeded to Gooty, where I met the Union Panchayat and the chief inhabitants of the town in reference to plague preparations. I then inspected the railway inspection camp at Tungabhadra. For the rest of the month, I was occupied in inspecting the plague-infected areas of Peddahotur and Molagavalli. During my inspection of Gooty, Hospet, and Bellary, I undertook plague inoculation.

In accordance with the usual custom in this Presidency, a written report was submitted on the result of each inspection made. In addition to this and routine sanitary and vaccination correspondence, special references for sanitary opinions from Government and local authorities (Collectors, Municipalities, and District Boards) were frequent, and exceptionally large in number.

Practically, Major Bannerman, the incumbent of the office of Inspector of Vaccination and Deputy Sanitary Commissioner, was not available for duty within the Presidency longer than four and a half months, in the aggregate, during the whole year. He, however, during his absence, conducted his usual share of office work, in connection with the Vaccination Department. He continued to attend the laboratory of M. Haffkine for instruction in the making of plague prophylactic serum until 19th April, 1898, when, after a temporary stay in Madras, he was placed at the disposal of the Government of India, for duty in Calcutta. He returned to Madras on the 31st August, 1898, when he was placed on special duty in the town of Madras for the introduction of anti-plague inoculation. He devoted himself to this work with much zeal, and, by means of popular lectures and demonstrations of the method, he did work of great importance in persuading the people to submit to this operation. The people displayed particular confidence in his methods. Three medical officers specially engaged for plague duty were also placed at his disposal, together with one lady Civil Apothecary. With this staff from September to the end of the year, 5,685 cases had been inoculated in the City of Madras.

The endeavour to provide an educated class of Certificated Sanitary Inspectors in this Presidency, in lieu of the so-called "Sanitary Inspectors" of the old type, whose comprehensions of their functions usually extended no further, in sanitary matters, than to see that the conservancy staffs were at their posts, whilst even this useful duty was interfered with by Chairmen requiring of them the duties of tax-collectors, has progressed favourably. Gradually, under the ruling that those who had no more than five years' service must qualify or leave their posts, men who have undergone a fair training in theoretical and practical hygiene have replaced them. Inspection of their diaries (which

form their media of communication with Chairmen of Municipalities) shows that many thoroughly sound suggestions have been excogitated. They now form a distinct factor in the sanitary advance of the Presidency, in that having adopted sanitation as a profession, they have influence amongst the inhabitants in bringing hygienic truths home to them. But, whilst this advance has been secured in municipalities, it seems most unreasonable that Local Fund areas should, with few exceptions, be unprovided with any staff that can deal with sanitary matters. It is to be hoped that the introduction of the revised Local Boards Act (Madras Act No. V of 1884) will secure the necessary funds and organization. The movement has attracted a well-educated and respectable class of young men, and, if nothing occurs "to put back the hands of the clock," the profession of a Certificated Sanitary Inspector in this Presidency should be one which should carry with it much respect. From the class assembled in 1898, not less than 55 matriculates were rejected, on account of the want of sufficient accommodation. In the meantime, there is a tendency for men of still better educational status to undertake sanitary work, who. find themselves debarred from obtaining any qualification other than that of the Licentiate of Sanitary Science of the Madras University, which can only be given to medical men. Whilst I hold that for the post of administrative Health officers, it is essential that a medical education should be undergone, I do not see that it is requisite where executive sanitary work is required. Given a good general education as a foundation, an excellent executive staff could be evolved, by demanding a special course of study from those who have not been put to the unnecessary toil of being qualified as medical men in the first place. In this connection, it must be remembered that there are large numbers of well-educated young men available,* whose services could be secured at a considerably smaller sum than qualified medical men—possessed of the same general educational status. Under these circumstances, I have placed myself in communication with the Director of Public Institution (owing to whose liberal views of matters educational, it has been possible to adapt existing examinations for the requirement of Sanitary Inspectors) with the object of ascertaining whether it is not possible to place before Government a scheme for a higher grade of sanitary executive officers. My suggestion is that candidates should have passed the F.A. examination, and that thereafter they should undergo a course of twelve months' training in subjects that would go towards making the necessary ideal standard. I believe, in this period, it would be possible to impart to them the main truths of theoretical and practical chemistry, bacteriology, physiology, pathology, medical diagnosis (human and veterinary), sanitary engineering, and general sanitation, that would render them valuable acquisitions to the sanitary service of the Presidency. Such a movement demands, on the one hand, that it should be possible to give a special diploma, and, on the other, that Government will insist on Local Fund bodies following the example of municipalities by employing sanitary staffs. My report embodied in G.O., No. 435, Public, dated 17th April, 1897, shows that a Vaccine Institute could be maintained and a complete sanitary and vaccination staff be organized, at an increase over present demand upon municipal income of 1·82 per cent., and a total cost for District Boards that would be covered by 4·85 per cent. upon their incomes.

Up to the end of the year, 64 Certificated Sanitary Inspectors were employed in municipalities, 12 in District Boards, and 69 were on special plague duty. In not a single instance was any complaint received as to the conduct of any Certificated Sanitary Inspector. Of the 98 temporary Sanitary Inspectors on plague duty, it cannot be said that all were equally efficient, or that no complaints were received as to them. Nevertheless, considering the hasty manner in which it was necessary to select and train them, I think they proved of very great utility. Six Certificated Sanitary Inspectors were, after two months' training in the Mysore Government Vaccine Institute, admitted to the Vaccination Department as Deputy Inspectors of Vaccination.

In reference to plague administration, Government adhered to the principles of "Observation" as opposed to quarantine, alluded to in the Personal Proceedings of the preceding year's report.

Following the heavy incidence of plague in the Mysore territory, during the last five months of the year, the disease was imported in 96 separate localities, in a total of eleven districts of this Presidency. In 95 localities, plague was imported 223 times. In 11 of these, importation was repeated from four times to over thrice that number of times. Thus, in Madras† 12 separate instances of importation were detected. Yet, the City of Madras remained free from plague, and in only 20 localities of 5 districts was it reported as indigenous, up to the end of the year. It is fair to argue that the progress of plague,

* During the last five years the Madras Uuiversity conferred the degree of B.A. in 2,120 cases.

† Since the first appearance of the disease in Bombay up to May, 1899, 18 cases have been imported, and have been duly isolated.

so long at least as it is confined to human beings, can be absolutely checked by a correctly worked "surveillance system," backed up by isolation of the sick, and the prompt application of sanitary measures. This is, of course, nothing but what might be expected. But, it is possible to argue that we are not acquainted with how many instances of plague may have been imported, and yet no indigenous plague has followed. This argument is tenable; but, having regard to the certainty with which plague slowly but surely spreads where concealment has been effected, the chances are greatly in favour of the supposition that the system really effectively kept touch of all arrivals from infected areas. I refer to this subject, as the natural tendency is to point to the heavy expenditure necessary for the support of the staff required to work such a method, and, secondly, to show that of so many thousands of cases that were inspected, so few really turned out to be plague. But it seems to me that the chances would have been 100 to 1, that each case detected would, if it had been undiscovered, have led to indigenous plague in the locality concerned, and that, consequently, not only have the people in these places been spared an unnecessarily early visitation from the disease, but they have been spared the loss of lives and money that must follow its appearance, compared to which the expenditure necessary for the staff must be insignificant. It is apt to be felt too that perhaps this escape of localities was not so much due to the precautions taken as to some fortuitous circumstances, depending upon the inability of the plague microbe to accommodate itself to to its environment. This factor undoubtedly does modify the chances of spread and, probably, the virulence of the microbe, but it obviously is very methodical and persevering in its efforts to overcome all difficulties, and it seems to me that, given time and season, there is no place in this Presidency that can be regarded as safe from the possibility of plague importation, and subsequent spread. In no instance has a case of plague been reported as having originated from infected articles received from any locality outside the Presidency. The origin of the disease has always been found to be due to human beings suffering from the disease, arriving from an infected locality. Evacuation of indigenously affected areas has been found, as in all epidemics of this disease that history has recorded, the best sanitary measure. M. Haffkine's anti-plague prophylactic has also its sphere of utility, and Government has done its best to encourage its use. I have, however, consistently opposed advice tendered to Government from time to time by other officers to neglect, or abolish, necessary sanitary measures in favour of solely practising inoculation. A total of 5,685 anti-plague inoculations was performed in the Madras town and 10,532 in the Presidency generally, up to the end of December, 1898. I have not put on record any sanitary experiences in this report as to plague, as I understand these will be dealt with by the Plague Commissioner.

Sanitary Engineering.

In the year under review, which was the ninth since the organisation of the department, the Sanitary Engineer visited fifteen towns and the Assistant Sanitary Engineer twelve, against ten and eight, respectively, in 1897.

The extension of the water-works at Conjeeveram at an estimated outlay of Rs. 50,401 was undertaken during the year, and more than 86 per cent. of the allotment was spent before its close.

Four surveys in connection with water-supply were completed during the year and one drainage and five water supply schemes were prepared and submitted either to the Sanitary Board or to Government. The schemes for improving the water supply of Ootacamund, for the extension of that of Tanjore and for the drainage of the Tanjore Fort were sanctioned by the Government during the year, the first and the third for execution by the Public Works Department, and the second by the Sanitary Engineer. The water-works in Trichinopoly were visited by the Sanitary Engineer and those in Madura, Dindigul and Tanjore by the Assistant Sanitary Engineer, while the pumping stations at Kurnool, Conjeeveram, Dindigul, Trichinopoly, Cuddapah, Tanjore and Madura were inspected and reported upon by the Inspector of Steam Boilers and Prime Movers. Thirteen type designs for sanitary works were prepared by the Sanitary Engineer and his advice was obtained by the Sanitary Board in 73 cases.

Sanitary Board.—The constitution of the Sanitary Board remained the same as in the previous years; but the rules for the conduct of its business were slightly modified by the addition of a rule making it incumbent on Collectors to consult the Sanitary Board whenever, in laying out house sites near railway stations, there arise

special difficulties not provided for in any general rules which the Board of Revenue may issue. The Board scrutinised plans and estimates for 36 Municipal and 78 Local Fund Works, estimated to cost £32,636 in the aggregate. Schemes for the water-supply of Vizianagram, for the extension of the water works at Kurnool and Tanjore and for the drainage of a portion of the Kumbakónam town were examined and laid before Government, and proposals in connection with nineteen other schemes, for which, however, estimates had not been prepared, were considered by the Board. The Board has also approved for issue thirteen type designs, and sent a circular to all local bodies requiring that proposals for repairing and improving tanks hitherto used indiscriminately for bathing, washing and drinking, purposes should include separate provision for drinking purposes so as to secure to the populations concerned a supply of pure drinking water.

ABSTRACT OF THE REPORT OF THE SANITARY COMMISSIONER FOR BOMBAY FOR 1898.

(*Lieutenant-Colonel J. W. Clarkson, I.M.S.*)

General Population.

European and Eurasian Vital Statistics.

The European civil census population of 1891 in the Bombay Presidency, exclusive of Cantonments in quasi-foreign territory, is 18,486. During the year 1898, 246 births and 243 deaths were recorded against 257 and 290 in 1897—a birth-rate of 13·31 per 1,000 against 13·90 in 1897 and a death-rate of 13·14 against 15·69. By sexes 141 males and 105 females were born against 119 and 138 in 1897, and, as regards deaths, 145 males and 98 females died against 170 and 120 in 1897.

The Eurasian census population of 1891 is 8,519. During the year 1898 the births amounted to 123 against 134 in 1897 and the deaths to 169 against 240—the rates being 14·44 per 1,000 against 15·73 in 1897 and 19·84 against 28·17. Of those born, 64 were males and 59 females against 72 and 62 in 1897; as regards deaths, 93 males and 76 females died against 123 and 117 in 1897.

The causes from which deaths among Europeans and Eurasians were recorded are given in the following table:—

Causes of deaths.		EUROPEANS.				EURASIANS.			
		1898.		1897.		1898.		1897.	
		Number of deaths.	Ratio per 1,000 of population.	Number of deaths.	Ratio per 1,000 of population.	Number of deaths.	Ratio per 1,000 of population.	Number of deaths.	Ratio per 1,000 of population.

* As the population for the cantonments in quasi-foreign territory is not obtainable, the ratio of deaths cannot be worked out. The deaths from plague are included under fevers. Figures in block type denote deaths from plague.

No deaths among Europeans and Eurasians from either cholera or small-pox were recorded during the year 1898. In 1897 there were 10 deaths from cholera among Europeans and 3 among Eurasians. From small-pox there was only one death, and that occurred among Europeans.

In the City of Bombay during the year 1898 there were among Europeans 13 deaths recorded from plague against 20 in 1897. In the collectorate of Poona there was among Europeans one death due to plague. Among Eurasians there were 23 deaths recorded from plague, of which 22 took place in the City of Bombay, and 1 in the collectorate of Poona. In 1897 there were 44 deaths recorded from plague among this community.

Native Population—Vital Statistics.

Births.—In the Presidency of Bombay, including Sind, during the year 1898, there were 582,371 births registered against 629,693 in 1897. The recorded births for the year under report were less by 47,322 than the number registered in the previous year and also less by 70,635 than the decennial mean ending 1897. By sexes there were 302,635 males and 279,736 females against 327,573 and 302,120 in 1897.

The following table shows the number of births registered in each year from 1888 to 1898, their ratios per 1,000, and the proportion of males to females :—

Years.	Population.	Number of Births registered.			Ratio per 1,000 of Population.			In every 100 Births there were		For every 100 male Births the females were
		Males.	Females.	Children.	Males.	Females.	Children.	Males.	Females.	
1888	16,454,414	330,316	304,377	634,693	20·07	18·50	38·57	52·04	47·96	92·15

Mean for 10 yrs.	18,110,566	339,389	313,617	653,006	18·74	17·32	36·06	51·97	48·03	92·41
1898	18,820,346	302,635	279,736	582,371	16·08	14·86	30·94	51·97	48·03	92·43

The recorded birth-rate for the year was 30·94 per 1,000 against 33·46 in 1897, and a decennial mean of 36·06.

The number of births recorded was lower than in the previous year in all the registration districts, except Gujarát. The low birth-rate during the early part of the year was most marked in districts which had suffered from famine and was no doubt due to the breaking up of family life, to reduced stamina leading to lessened fertility and to the reduced number of marriages during the worst period of the famine. The heavy mortality during 1897 and the plague were also, I think, causes of the decrease although no doubt minor ones.

Of the 24 collectorates and districts, the number of recorded births in 1898 was higher than in 1897 in the city of Bombay, Kaira, Panch Mahâls and Karáchi. The remaining collectorates show a decrease as compared with 1897. The city of Bombay, as usual, recorded a low birth-rate. The decennial mean up to 1895 is 19·29. In 1897 the rate per 1,000 was 11·29 and in 1898 13·08, but owing to plague these were exceptional years.

As regards the Central Registration District, the Deputy Sanitary Commissioner remarks: "the birth-rate in 1896 was 39·54; in 1897 33·56 and in 1898 29·50. The fall during these three years has been in every collectorate and is very nearly equal in all, but has been greatest in Ratnágiri. This collectorate is the one in which there has been least famine and plague, but the prevalence of plague in Bombay City has greatly interfered with the earnings of a large number of the population, and this combined with a certain amount of scarcity, no doubt, has led to distress and a lessened birth-rate. The small birth-rate in the Central Registration District during 1898 is no doubt due to the after effects of famine and to a certain extent to the very heavy mortality during 1897."

The Deputy Sanitary Commissioner, Southern Registration District, remarks that the birth-rate has been less throughout the whole district in consequence of emigration on account of famine and plague.

The recorded birth-rates among the urban and rural populations of the Presidency were 24·05 and 31·91 against 24·85 and 34·36 in 1897. Except in the collectorates of Khándesh, Ratnágiri, Bijápur, Kánara, Kaira, Panch Maháls, Ahmedabad and throughout Sind, with the exception of the Upper Sind Frontier, the birth-rates were higher among the rural than in the urban population. The urban rates were in many places greatly affected by the exodus caused by plague, and so also were rural rates in some parts, but not, I think, to so great an extent. In the collectorate of Broach and in the district of the Upper Sind Frontier the birth-rates among the rural and urban populations were nearly the same, 40·48 and 40·55, respectively, in the former, and 26·20 and 26·27 in the latter.

Out of 56 towns in the Presidency, 16 had a birth-rate exceeding 40 per 1,000. Poona, Ahmednagar, Sholápur, Belgaum, Bombay, Alibig, Sátára, Panvel, Hubli and Thána have very low birth-rates. This, in the case of Bombay, Poona, Ahmednagar, Belgaum, Sátára and Hubli, is chiefly due to the decrease in population owing to the exodus caused by plague.

Deaths.—Among the civil population in the rural, town, and cantonment circles in the Presidency, 548,825 deaths were registered during the year 1898. In 1897, 749,916 deaths, or 201,091 more than in 1898, were recorded.

The following statement shows the number of deaths recorded in each year since 1888 :—

1888	...	468,039	1892	...	611,742	1896	...	596,472
1889	...	518,562	1893	...	511,831	1897	...	749,916
1890	...	463,616	1894	...	607,179	1898	...	548,825
1891	...	513,132	1895	...	538,540			

Of the total deaths registered, 288,796 occurred among males and 260,029 among females, against 396,154 and 353,762, respectively, in 1897. The death-rate per 1,000 in 1898 was 29·16 against 39·84 in 1897 and a decennial mean of 30·80. The millesimal rates of males dying to males living was 29·66, and of females dying to females living was 28·63. In 1897 these ratios were respectively 40·68 and 38·95. For every 100 females who died, 111·06 deaths among males were recorded, but these proportions vary considerably in the following collectorates and districts :—

In Thána the ratio of male to female deaths was			113·45 per cent.
„ Bombay	do.	do.	144·48 „
„ Ahmednagar	do.	do.	113·31 „
„ Karáchi	do.	do.	142·35 „
„ Hyderabad	do.	do.	129·17 „
„ Thar and Párkar	do.	do.	115·14 „
„ Shikárpur	do.	do.	114·69 „
„ Upper Sind Frontier	do.	do.	122·16 „

The highest death-rate occurred in the Southern Registration District, which had the misfortune to suffer from both plague and cholera; the former to a considerable extent. All the other districts, except the Western Registration District, were much below the decennial mean, notwithstanding the presence of plague in some of them. The almost total absence of cholera, except in the Southern Registration District, was in favour of a low death-rate; there was no cholera at all in Sind.

Notwithstanding 10,537 deaths from plague in the Central Registration District, the death-rate in this district was considerably below the decennial mean. Plague in Bombay City was the cause of the death-rate of the Western Registration District exceeding the decennial mean, but it only did so to a slight extent.

There were high death-rates very much over the decennial mean in the City of Bombay and in the collectorates of Belgaum and Dhárwár—these were due to plague. In all the

other collectorates, except Thána and Panch Maháls, the rates were below the decennial mean—in most cases very considerably so. The Deputy Sanitary Commissioner, Gujarát Registration District, remarks that the increased death-rates in the collectorates of Broach and Panch Maháls are due to their being affected with plague during the year. The death-rates in 1898 by collectorates ranged from 64·03 per 1,000 in the City of Bombay to 11·04 in the collectorate of Hyderabad. In 1897 the maximum and minimum ratios (58·88 and 15·92) occurred in the same collectorates.

Deaths by sexes.—In the City of Bombay, Broach, Kaira, Panch Maháls, Thar and Párkar and Shikárpur, the recorded death-rates of females were higher than those among males. In Sátára, Kánara, and the Upper Sind Frontier, the death-rates of males and females were about equal. In the remaining collectorates the death-rates of males exceeded those of females. In 1897 the female death-rates exceeded those among males in the City of Bombay, Shikárpur, the Upper Sind Frontier, and Thar and Párkar.

Deaths by ages.—The figures given below show the total deaths in 1898 under different ages, as also the ratios per 1,000 living, calculated on the population of each age-period enumerated at the Census of 1891 and the percentage of total deaths :—

Age-period.	Population according to Census of 1891.	Number of deaths.	Ratio per 1,000 of population.	Percentage on total deaths.
Under 1 year	680,472	99,590	146·35	18·15
1 and under 5 years	2,178,646	90,732	41·65	16·53
5 and under 10 do.	2,615,588	33,696	12·88	6·14
10 do. 15 do.	1,820,754	24,889	13·67	4·54
15 do. 20 do.	1,470,976	19,102	12·98	3·48
20 do. 30 do.	3,410,817	55,217	16·48	10·06
30 do. 40 do.	2,765,949	55,326	20·00	10·08
40 do. 50 do.	1,841,976	46,115	25·04	8·40
50 do. 60 do.	1,117,120	42,298	37·86	7·71
60 and upwards	918,048	81,860	89·17	14·91
Total	18,820,346	548,825	29·16	100·

As compared with last year the table shows that there has, in the present year, been a decrease in the percentage of deaths under 5 years and an increase between 20 and 60, which is most marked between the age of 20 and 40. These variations are no doubt due to the almost complete absence of cholera and famine, and to the increase in plague during the present year. The variation is most marked in the decrease of deaths below 5, and this would be no doubt due to the decrease of famine. The absence of cholera would tend to reduce adult deaths, but this has no doubt been counteracted by the increase in plague, which would tend to swell them considerably.

Deaths by causes.—The subjoined table shows the deaths in 1898 arranged according to the specified causes laid down by the Government of India, and contrasted with the results for 1897 and with the decennial mean. The "causes of death" will be briefly noticed in the next section :—

Causes of deaths.	Mean for 10 years, 1887–1896.		1897.		1898.	
	Number.	Ratio per 1,000 of population.	Number.	Ratio per 1,000 of population.	Number.	Ratio per 1,000 of population.
Cholera	28,672	1·58	57,109	3·03	4,368	·23
Small-pox	3,720	·21	3,835	0·20	1,834	·10

			46,944	**2·49**	**86,191**	**4·58**
Dysentery and diarrhœa ...	42,783	2·36	85,966	4·57	56,789	3·02
Injuries	6,029	·33	6,907	0·37	6,984	·37
Other causes	91,989	5·08	143,503	7·62	176,335	9·37
All causes	557,903	30·80	749,916	39·84	548,825	29·16
			46,944	**2·49**	**86,191**	**4·58**

N.B.—Figures in thick type denote deaths from plague which have been included under "Fevers."

The death-rate for the year was 29·16 and the decennial mean is 30·80. It is therefore seen that notwithstanding the presence of plague, the year—judged by the number of deaths—was a healthy one. If there had been no plague the year might have been described as a healthy one up to the end of April, a very healthy one from April to October, and about a normal one from then up to the end of the year. As things were, plague reduced the first period to a normal one, affected the middle very little, but converted the last into a very unhealthy one. Of course, this is taking the Presidency as a whole, otherwise, districts varied greatly. Compared with the previous year there is a great improvement as shown by the rates 39·84 for 1897 and 29·16 for 1898. Last year the the death-rate was greatly increased by the effects of famine, by a very heavy cholera mortality, and by plague, and was considerably above the decennial mean (39·84—30·80).

The recorded death-rates among the urban and rural populations of the Presidency were, respectively, 47·88 and 26·55 per 1,000 of population against 56·73 and 37·49 in 1897. Among the rural population the death-rates were higher than in the urban population in the collectorates of Dhárwár and Kánara where the rural death-rates exceeded the urban by 8·13 in the the former and 8·43 in the latter.

Chief Diseases.

Cholera.—During the year 1898 there was practically no cholera except in the Dhárwár collectorate, and Sind for the second year in succession was entirely free. There were in all 4,368 deaths recorded compared with 57,109 in 1897, and with three exceptions this is the lowest record during the last 20 years; the year 1897 gave by over 15,000 the highest record during the same period. The ratio per 1,000 was 0·23 as compared with 3·03 for last year and a decennial mean of 1·41. Of the 4,368 deaths no less than 4,054 occurred in the Dhárwár collectorate. Bombay City gave a few deaths every month, but the total for the year amounted to only 104. As already mentioned Sind was entirely free, and 4,054 deaths occurred in the Dhárwár collectorate; the Poona collectorate gave one death, as did also Ahmedabad collectorate; the collectorates of Sátára and Ahmednagar gave 2 each, the collectorates of Bijápur and Sholápur 3 each, Thána collectorate 7, Kolába collectorate 15, Kánara 79, and Belgaum collectorate 97.

In December, 1897, there were 121 deaths reported from eight districts. These districts were Sholápur, Khándesh, Ratnágiri, Kánara, Thána, Bombay City, Kolába and Dhárwár. It is not necessary to follow the disease month by month as, with the exception of the City of Bombay, Belgaum, Dhárwár and Kánara, there were only scattered cases at intervals. The City of Bombay has already been disposed of: Belgaum collectorate had one case in February, and then a few cases every month from May to the end of the year, but the total only amounted to 97. In the Dhárwár collectorate there were 4,054 deaths, and these were spread over every month of the year; the disease increased in April, reached its maximum in August, lingered in September and October, and died out in December. In Kánara there were deaths in April and May, when more than half the total (79) occurred, and the remainder took place in July, August and September.

By seasons: 2,580 deaths occurred in the rainy season of 122 days; 1,003 in the hot and dry season of 61 days; 348 in the cold season of 121 days, and 437 in the hot and damp season of 61 days.

Out of 220 rural circles 27 were affected by cholera during the year. In 18 of these the death-rate was below 1 per 1,000 of population. As already mentioned, the disease was almost exclusively confined to Dhárwár. Out of 13 tálukas of this collectorate 8 were affected.

Out of 56 town circles 14 were affected during the year. Of these, 7 had only one death each and 2 had two each. There was no cholera in any of the cantonments.

Out of 7,751 villages in the districts affected by cholera, 324 or 4·18 per cent. were affected during the year. The highest percentage (21·80) took place in the Dhárwár collectorate, where out of 1,303 villages 284 were affected. In the collectorate of Belgaum the percentage was 1·77, while in the remaining affected collectorates the percentages were below 1 per cent.

Small-pox.—There were 1,834 deaths from small-pox (946 males and 888 females) against 3,835 in 1897 and a decennial mean of 3,720. The year's mortality was the lowest on record with one exception during the last twelve years. The Western Registration District was the most affected; after it came the Southern and Central Registration

Districts ; Sind was very slightly affected, and the Gujarát Registration District gave only 10 deaths. The deaths were 2,001 less than in the previous year, and the ratio per 1,000 was 0·10 against 0·20 last year and 0·21, the decennial mean. These figures may be considered very satisfactory, and they testify to the exceedingly good vaccination work which now for some years has been done in the Presidency. After the experience of the famine year of 1877 and the following year, when 27,369 and 4,475 deaths from small-pox were recorded, it is very satisfactory to be able to state that, notwithstanding much better registration, the famine year of 1897 and the following year gave only 3,835 and 1,834 deaths from the same disease. This result is chiefly to be attributed to the progress vaccination work has made since the former period.

As regards collectorates, there was an increase in Násik and Thána in the Western and Bijápur and Kánara in the Southern Registration Districts. The highest death-rate 0·42 occurred in Khándesh and the lowest 0·01 in Ahmedabad. There was only one death in each of the following collectorates :—Surat, Kaira, and Panch Maháls : Ratnágiri, Broach and Shikárpur were entirely free.

According to age, 27·59 per cent. of the small-pox deaths occured amongst infants under one year of age, whilst 51·69 per cent. took place amongst children over 1 and under 10, the remaining 20·72 being among persons over 10 years of age.

Fever.—There were 302,515 deaths registered under the heading "fever"—161,213 males, and 141,302 females. This shows a decrease of 150,081 as compared with the previous year : the decennial mean is 384,710. The above figures include deaths from plague ; excluding this disease there were 216,324 deaths ascribed to fever as compared with 405,652 in the previous year, and a decennial mean of 379,806. With the agency at our disposal for the registration of deaths, and in a country where so many diseases are by the people called fever, it is inevitable that many diseases must be returned under the head of "fever" which do not rightly belong to this heading. This has always been the case, and although these fever deaths cannot be relied on as being all due to fever, they can, when taken for a number of successive years, give an indigation as to the prevalence or otherwise of the common fevers of the country. The carrying out of plague measures in some of the towns of the Presidency has led to very much more accurate registration in them. Some municipalities are, I think, improving in this respect, and it is to be hoped that this may continue, and that in time it may be possible not only to obtain more accurate registration, but to add to the headings at present in use.

The death-rate under the heading "fever" was 16·07 per 1,000 compared with 24·05 for the previous year, and a decennial mean of 21·24, and this notwithstanding the fact that deaths from plague are included under the heading. In only one district was the rate higher than the rate last year and the decennial mean, and that was in the Southern Registration District, and was undoubtedly due to a high mortality from plague in the collectorates of Dhárwár and Belgaum ; in all the other districts it was exceptionally low, especially in the Central. If it had not been for the large number of plague deaths, the rate for the Presidency would have been very much lower. For the Western Registration district the rate was very much increased by the large number of plague deaths in Bombay. The rate in Ahmednagar collectorate was very low, and is more than one quarter below the decennial rate. This would almost lead one to suppose that deaths usually registered under "fever" are being entered under some other head, but the rates under "dysentery and diarrhœa" and "other causes," under which cases would fall if excluded from "fever," are in the former only very slightly increased, and in the latter, although doubled, do not show a greater increase than in a great many other collectorates whose decreases under "fever" are not nearly so great as in Ahmednagar.

There was a rise in all districts in the number of deaths returned under "other causes," but even if the increases were added to the "fevers" it would not, except in the case of the Southern Registration district, make any of them over the decennial mean, and considering this and the low rate under "fever" and the fact that a large number of plague deaths are included, it may be taken that, as regards the common fevers of the country, the year was a healthy one, and, also, that no disease which would be likely to be returned under the heading "fever," except plague, was at all widely distributed or fatal.

In spite of the nearly double increase in the plague mortality the number of deaths in each month during the year is less than in the corresponding month of the previous year, and, excepting October and November, is less than the decennial mean. In June the lowest mortality for the year was as usual reported, and in July a rise took place which reached its maximum in October ; November gave nearly the same number of deaths as

October, but in December there was a decided fall. Excluding plague deaths the number every month was considerably less than the corresponding months of last year and of the decennial mean, and except that the numbers were very low the monthly variations as compared with the decennial mean were normal.

Dysentery and Diarrhœa.—Dysentery and diarrhœa caused the deaths of 30,256 males and 26,533 females, or a total of 56,789 persons against 85,966 in 1897, and a decennial mean of 42,783—a decrease of 29,177 against the last year, but an increase of 14,006 over the decennial mean. The deaths ascribed to "dysentery and diarrhœa" during the ten years preceding 1897 showed only very slight variations, but in 1897 the deaths due to these diseases showed a considerable increase and amounted to nearly double that of any of the ten years already mentioned. The increase has been continued during the present year, and, although much smaller, the total is still considerably over any of the ten years previous to 1897. The rate (3·02) although still high was lower than in the year 1897 (4·57), but was still over the decennial mean (2·36). The increase as last year is chiefly in the Western and Central Registration districts and is most noticeable in those parts lately affected by famine, with the exception of Bijápur which showed a decrease as compared with the decennial mean. The collectorates of Násik, Poona, Sholápur and Sátára, which last year had a very high rate, still show a rate considerably over the mean, and Sholápur as last year continues to head the list, although not so markedly. All these collectorates suffered from famine in 1896–97 and some to a certain extent in 1898. Sholápur, which shows the highest rate in 1897 and also in 1898, was the one most severely affected by the famine as well as the one in which it continued the longest. In my opinion the prevalence of these diseases is chiefly due to the after effects of the famine. The Southern Registration district, which last year showed an increase over the decennial mean, has this year fallen below it. The variations in the Registrations districts of Gujarát and Sind are very small and call for no remark.

Injuries.—During 1898, 3,973 males and 3,011 females, or a total of 6,984 persons met with violent deaths. The mortality from these causes is more by 77 than that reported in 1897.

Of these 3,004 occurred from drowning, 1,451 resulted from snake-bites, 660 from wounding, 223 from hanging, 115 from poisoning, 79 from attacks by wild beasts, and 1,452 from other causes.

Other Causes.—The recorded deaths from causes other than those specified number 176,335, of which 90,033 occurred among males and 86,302 among females. The total for 1897 was 143,503, so there is an increase of 32,832. Under this head all deaths are included which cannot be classed under cholera, small-pox, fever, dysentery and diarrhœa, or injuries. They have been increasing gradually for the last ten years, and are now more than double what they were ten years ago. The increase became more pronounced in 1897, and this has been continued during the present year. At first sight this late increase would at once be put down to increased accuracy in registration owing to famine and plague operations, but the subject is not quite such an easy one as at first appears, as there are other things which influence the rates.

Sanitary Works.

All available information under these sections has been thrown in a tabular form, and will be found in Appendices IV. and V.*

There were 166 Municipalities (compared with last year (167), Matar in Kaira and Pussesavli in Sátára district have been abolished, and Kharda in Ahmednagar newly established) in the mofussil, with a population of 2,231,254 souls and an income of £355,080. Out of this income £174,802, or 49·23, were allotted for sanitary works, and out of this allotment £161,790, or 92·56 per cent., were spent. Out of the total expenditure, £70,052, or 43·30 per cent., were spent on conservancy; £34,534, or 21·34 per cent., were spent on improvement of water-supply; £8,129, or 5·02 per cent., on improvement of town sites; £2,781, or 1·72 per cent., were spent on construction and repairs of markets and slaughter-houses; £2,119, or

* Not reprinted.

1·31 per cent., were spent on sanitary arrangements during fairs and festivals, and £44,177, or 27·31, were spent on other sanitary objects, including construction and repairs of tanks, &c.

The Bombay Village Sanitation Act of 1889 has been introduced in 17 other villages during the year 1898, making a total of 299 since the introduction of the Act in the year 1895. At Andersal in the Násik collectorate the Act has been suspended for the present. In the village of Mirajgaon in the Ahmednagar collectorate the Sanitary Act was introduced in 1895, but the people of the village having objected to the establishment of the sanitary committee the proclamation was cancelled in 1896 in accordance with Clause 3 of Section 6 of the Act. In May 1898 the Act was re-introduced into the village and a committee established under Part II. without funds.

Personal Proceedings and General Remarks.

The year 1898 has witnessed a continuance of the plague in the Bombay Presidency and is chiefly remarkable for its spread in the Southern Marátha Country. A brief account of its progress in the Presidency is appended.

The Sanitary Department has been much disorganised during the year owing to the Deputy Sanitary Commissioners and Inspectors being called away by Government for other purposes and no men being supplied to take their places.

A mixed Commission consisting of three medical men from England and two members of the Indian Civil Service, with a secretary, also a civilian, was appointed and commenced its work on 28th November, 1898.

The Committee was directed to inquire into—

1. The origin of the different outbreaks of plague.
2. The manner in which the disease was communicated.
3. The effect of curative serum.
4. The effect of preventive inoculation.

All purely medical questions.

The control of the plague operations was, during the year, under the direction of a member of the Indian Civil Service who was termed the Plague Commissioner.

In the course of the year 4 Native States have been permitted to maintain their own vaccination establishments. This means that they appoint their own vaccinators and supervising staff, and all that the Sanitary Department have to do with them is that the Sanitary Commissioner and his Deputies can inspect the work from time to time. This will mean very little control over the vaccinators, as, owing to the large areas in their charge, Deputy Sanitary Commissioners cannot often inspect, and the vaccination will deteriorate.

The camps which had been kept open to afford relief to workers (two in the Sholápur and one in the Poona district), till the harvest was assured and work was obtainable, were closed finally on the 28th October, 1898.

The City of Bombay Improvement Trust Bill was passed into law, and under it a Board has been appointed on which three medical men have seats. The first meeting was held on 24th November, 1898. It will probably take some time before any results are arrived at, and, in my opinion, one method of preventing overcrowding would be to prohibit the building of any more factories or mills or any concern employing a large amount of labour in the Island of Bombay, unless the owner or company will put up sufficient and suitable accommodation for their employés, not necessarily in the compound, but within reasonable distance.

Last year a very important sanitary measure was directed to be adopted by Government in Government Resolution No. 4512, in the General Department, dated 19th August, 1898, and the introduction of a "Village Sanitary Inspection Book" was ordered in such villages only as may be approved by the Commissioner of the Division in which they are situated. This measure, which will result in great sanitary progress, should be extended to all villages.

It is to be hoped that Government will bear in mind the need of strengthening the Sanitary Department and add to the staff a Bacteriologist as soon as funds permit, and take the first steps towards founding a Sanitary Institute of Public Health on the lines suggested in my report for 1897.

If the latest methods of dealing with sewage are to make any headway and secure public confidence, a bacteriologist to keep on experimenting and controlling operations, will be absolutely necessary.

Owing to the regulations for combating plague, the registration of deaths has been rendered much more accurate, and this increased accuracy should be kept up even when the plague has passed away. Also a good deal can be done to encourage the registration of births by refusing to accept, after the lapse of a certain number of years, declarations before Magistrates and horoscopes as evidence of age.

Plague.

The figures shown are from returns received in this office and do not tally with returns elsewhere published. In the general returns the deaths are included under the heading "Fever." At the end of 1896 there had been a total of 2,909 attacks and 2,086 deaths from plague, 61,093 attacks and 46,944 deaths were recorded during 1897 and 110,369 attacks and 86,191 deaths in 1898 ; the table on the opposite page gives the progress of the disease by months in each collectorate for the year under report.

Khándesh.—Plague prevailed to a limited extent up to May, the greatest mortality (79) being in February. From May up to November there was only 1 attack. In November and December there were 35 attacks and 21 deaths. No town circle was affected. The total for the year was 16 villages affected, 289 attacks and 230 deaths.

Násik.—The outbreak, which had begun in August 1897, reached its maximum (354 deaths) in January and was on the decline in February. After that month the mortality fell rapidly and the collectorate was free in May. There were a few cases in July, and in August the deaths amounted to 269 ; they increased during September and declined during October and November, but in December there was a slight rise, and the month showed a mortality of 161. The town circles of Násik and Sinnar and Málegaon town suffered during the first three months of the year—the latter rather severely during January. In all 71 towns and villages were affected, and there were 2,699 attacks and 1,951 deaths.

Thána was affected during the whole year. In January the disease was on the increase, and this continued until May, when there was a fall, which, however, only lasted during June. In July there was a large and sudden increase in the mortality, and the deaths continued to increase during August, but in September there was a substantial fall, which continued during October and November ; in December there was a slight rise. The mortality was heaviest during the latter half of the year. There were a few cases in nearly every month of the year in the town circles of Thána and Bándra ; the former had most in August, September and October, and the latter from April to September. Bhiwndi town was severely affected ; the disease commenced in April and ended in October, and was at its height in August : there were in all 1,789 cases and 1,261 deaths. The total for the year was 95 towns and villages, 5,374 attacks, and 3,235 deaths.

Bombay City.—As in 1897 the disease was prevalent during the entire year. In 1897 it had reached its minimum in July, but from that month it showed an increase up to the end of the year ; this, although slight up to the end of November, was more decided during December and in January was very marked. The maximum deaths (4,973) were reached in March, in April there was a fall to more than half this number, and in May and June there was a very considerable fall. In July the mortality increased and continued to do so until October, the greatest number of deaths during this period being (709) during the latter month ; it fell greatly in November but rose again in December. The lowest mortality was in June, and by far the greatest number of deaths occurred during the first half of the year. The total for the year was 19,863 attacks and 18,130 deaths ; but there is very little doubt that many cases and deaths escape registration.

Kolába.—There was a little plague in Kolába up to July. The highest mortality being (238) in March. No cases occurred in July, only 1 case in August, and very few in September, October and November, and these were chiefly imported. In December there were 93 deaths. In all there were 46 towns and villages affected and 779 attacks, and 654 deaths.

	Total for the Presidency ..	7,646	6,203	8,254	6,811	7,607	6,651	4,928	3,773	3,599	2,759	1,581	1,003	3,671	2,490	8,892	6,515	14,500	10,952	22,361	17,227	17,129	13,777	10,201	8,030	110,369	86,191	1,188

Ahmednagar.—In January there were 152 deaths, after which they fell rapidly until in April the district was practically free and continued so until October, in which month, and until the end of the year, there were a few deaths, but they never amounted to more than 23 in any one month. Ahmednagar town circle was affected during the early months of the year; there were 101 deaths in January, but after this the disease rapidly declined. The totals for the year were 12 towns and villages, 398 attacks and 333 deaths.

Poona.—The disease, which had prevailed considerably, chiefly in the City of Poona, during the latter part of 1897, had in January shown a great and sudden fall, which continued until in May the district was practically free, and remained so until August, in which month there was a slight rise, which increased in October and November, but fell in December; during this period the highest mortality (328) was in October, there were 65 deaths in December. In January, Poona City was at the end of a severe epidemic which had commenced in August; during the succeeding month the epidemic rapidly declined, and the city was free at the end of April. In all there were 60 towns and villages affected, and 1,942 attacks and 1,355 deaths during the year.

Sholápur.—Plague had commenced in September, 1897, and had continued to increase until the end of the year. In January there was, as in the Poona district, although not to the same extent, a great and sudden fall, which continued until in April there were only 9 deaths, and in May none. In June the district was practically free, but in July the deaths rose, continued to do so in August, and fluctuated up to the end of the year. The greatest number of deaths (166) during this period was in October. Sholápur town was slightly affected during January and February, this was the end of a sharp outbreak which had occurred towards the end of 1897. The totals for the year were 80 towns and villages, 2,288 attacks, and 1,557 deaths.

Sátára.—This collectorate was affected throughout the year. The disease which had commenced in July, 1897, was on the decrease in December, and this decrease continued into the present year and reached its minimum (96) in April. The mortality then rose, but showed no very great increase until August, when the rise became more considerable, and in October had reached the maximum (1,987); it fell in November and December, and in the latter month had fallen to 560. All the tálukas except Malcolm Peit were affected, but nearly one-third of the deaths recorded were in the Sátára táluka. Sátára town in January was at the height of an epidemic which had commenced in October, 1897; in February the mortality fell considerably, and in May the town was free from the disease, but there was a slight epidemic in the latter part of the year. In the whole collectorate 220 towns and villages were affected, and there were 9,340 attacks and 6,918 deaths.

Ratnágiri.—In the first half of the year there was some plague, but the latter half was practically free. The highest mortality (167) was in April. There were 33 towns and villages affected, and 482 attacks and 374 deaths occurred.

Belgaum.—With the exception of the City of Bombay and Dhárwár this was the collectorate which suffered most during the year. The disease commenced in October, 1897, in December it had reached the maximum mortality of that epidemic (275), and then began to decline gradually until June, in which month it showed a rise, which continued until the maximum (5,352) was reached in October; a fall then set in, which continued up to the end of the year. Belgaum town was affected throughout the year; in January an epidemic which had commenced in October was at its height, but in February there was a considerable fall, which continued; cases, however, kept on occurring, and they considerably increased in August, and the town went through a much more severe epidemic than the previous one. The totals were 183 towns and villages affected, and 22,547 attacks and 16,301 deaths.

Dhárwár.—In 1897 there were a few cases every month from October to the end of the year, and this continued up to June of the present year, in which month there was a rise in mortality, which continued during July and August, and in September was very pronounced. The maximum (7,784) was reached in November, and it was not until December that there was any decided improvement. This collectorate was the one which suffered most severely in the whole Presidency. Belgaum had more towns and villages affected, but the mortality was much greater in Dhárwár and was 26·4 per 1,000. In Dhárwár town the disease commenced in July, reached its maximum in October, and in December had almost entirely disappeared. There were 120 towns and villages affected, and there were 34,494 attacks and 27,764 deaths.

Bijápur.—There were a few deaths during February and March, but none between that month and September; in the latter month the disease recommenced and gradually increased up to the end of the year. There were 414 deaths in December. The totals were 49 towns and villages affected, and 1,373 attacks and 979 deaths.

Kánara.—There was no plague until August, when 8 towns and villages became affected, and there were 76 attacks and 59 deaths distributed over the remainder of the year.

Surat.—In this collectorate the plague was present in every month of the year, both in 1897 and 1898. In January the disease was rising, and the maximum (577) was reached in February, after which the mortality declined until May. In June and July it again rose; in August there was a slight decrease, and after that a rapid one, until at the end of the year the collectorate was practically free. In January the City of Surat was in about the middle of an epidemic which was on the decline; there were, however, a good many cases up to the end of March, but during April the disease died out. In all there were 95 towns and villages affected, and 3,366 attacks and 2,552 deaths.

Broach.—There were only a few scattered cases until July, when there was a slight increase, followed by a larger one in August; however, this was not maintained beyond September, and the mortality declined with fluctuations up to the end of the year. The town of Broach was slightly affected during the latter part of the year, as was also Anklesvar. There were 19 towns and villages affected, and 580 attacks and 424 deaths.

Kaira.—There were a few cases up to June, but they were all imported, and no local cases occurred until September. From that month the disease increased up to the end of the year, but the greatest number of deaths in any one month amounted to only 234. There were 28 towns and villages affected, and 612 attacks and 445 deaths.

Panch Mahâls.—The disease appeared in October, and increased up to the end of the year, but there were in all only 272 attacks and 201 deaths in 15 towns and villages.

Ahmedabad.—There was no indigenous plague in this collectorate, only 10 imported cases and 6 deaths being reported.

Karáchi.—In Sind the disease was, with the exception of 2 imported cases in the Hyderabad collectorate, exclusively confined to the collectorate of Karáchi, and the only part of this district which was affected, with the exception of 8 cases at Kotri, was the town of Karáchi, in which there were 3,253 cases and 2,543 deaths. There were in addition 322 cases at various places in the collectorate, but they all originated in Karáchi town. The outbreak in the town of Karáchi was sudden and sharp; it commenced in April, and in May had reached its height. In June there was a considerable fall in mortality, and this was very much more marked in July and August, but a few deaths occurred monthly up to the end of the year.

Hyderabad.—In this collectorate the only cases reported were 2 imported ones.

In the whole Presidency there were 86,191 deaths from plague, and 1,188 towns and villages were affected, as compared with 46,944 deaths and 912 affected towns and villages in 1897. The number of deaths from plague in 1897 was nearly exactly the same as the cholera deaths during the worst cholera year in the previous 19 years. The heaviest mortality from cholera during the last 20 years occurred in the year 1897, but the plague deaths during 1898 exceeded this by 29,082.

The parts most affected were the collectorates of Dhárwár, City of Bombay, and Belgaum, and the rates of plague deaths per 1,000 in them were 26·4, 22·4, and 16·1 respectively. Sátára came next with a rate of 5·6, and then Karáchi, Thána, and Surat with rates which ranged from 4·8 to 3·9 per 1,000; Násik and Sholápur had rates of 2·3 and 2·08 respectively, the rates of the remaining affected collectorates were much lower. As already mentioned, the only parts of Sind which returned indigenous cases were the towns of Karáchi and Kotri; the former suffered severely, but the latter gave only 8 cases. Except for a few imported cases the collectorate of Ahmedabad was entirely free. With the foregoing exceptions all the collectorates in the Presidency were more or less affected. The rate per 1,000 for the various Registration Districts were as follow:—Western 5·35, Central 2·09, Southern 13·65, Gujarát 1·17, and Sind 0·95.

In January there were 6,203 deaths, and during February and March there were much about the same number. In April the deaths fell considerably, and continued to fall until the minimum (1,003) was reached in June. They rose a little in July, and in August and September there was a more distinct rise, and in October they reached the

maximum (17,227), after which there was a fall in November, and this continued and was very much more marked in December.

The year 1898 was remarkable for :—A very low birth-rate up to the end of July, one considerably above the average for the last four months of the year, and a rate for the whole year much below the normal ; a very low cholera mortality ; a largely increased plague mortality ; and a low death-rate from diseases—excluding plague—registered under the heading "Fever." Excluding plague, the year was one of the healthiest during the last 11 years. Prices of the chief food-grains, although still somewhat high in the Deccan, were very much lower than in the previous year. In Khándesh they were, as regards some food-grains, lower than the average, and this was also the case in Gujarát. The low death-rate, the increasing birth-rate, and the reduced mortality from dysentery and diarrhœa show that during the year the people were rapidly recovering from the effects of the famine of the previous year.

Report of the Sanitary Board for the Year 1898.

Preliminary.—Owing to the expenditure incurred by municipalities in connection with the plague, and to their reduced incomes from the restriction of trade due to the plague, almost every municipality has shelved the consideration of all important sanitary works ; and unless Government come to their assistance by relieving them of the whole, or of the greater part, of the debts they have incurred in connection with plague, it is certain that this stagnation will continue for many years. In every district municipality there are a certain number of members who are opposed to progress, and to any taxation, except in the cause of schools ; and their influence is materially strengthened when the municipality is already in debt. We would also suggest that the Government should deal more liberally with these municipalities in the way of loans for important sanitary works. In the North-West Provinces, Punjab, and Madras, a municipality can always not only get a Government loan for a sanctioned work of this nature, at 4 to 4½ per cent., for 20 or even 30 years, but also in most cases they get a large grant-in-aid ; whilst in this Presidency these municipalities are now forced to go to the open market, where 6 to 12 per cent. is demanded ; and even the lower of these rates is prohibitory, with their small means. Moreover, no municipality in this Presidency has ever got a grant-in-aid, although it is known that without this material assistance few of the important sanitary works in other provinces could have been carried out. Such an assistance is a powerful lever in inducing a municipality to agree to the extra taxation required for these works ; and we earnestly hope that the Government may be pleased to assist future schemes in this Presidency, as they are assisted in other provinces. Under the continued pressure of the plague authorities, the general state of improved cleanliness, noticed in the last report, has been maintained.

Shikárpur.—Nothing has been done here ; and, in fact, the municipality passed a retrograde resolution stopping the construction of the system of gutters by which the waste water from the numerous wells in the crowded town should be removed outside.

Sukkur.—Nothing has been done here. The water-works engines have been much neglected, and serious repairs will soon be necessary.

Hyderabad.—With very great difficulty the municipality were induced to order the urgently wanted new engines for the river pumping station at Giddu, by means of a temporary loan from Government. The new engines are to be triple expansion Worthington's ; and they are expected to begin working during the hot season. Plans and estimate for the remaining portion of the water-works, as indicated in last year's report, have been prepared by the Sanitary Engineer ; and as the finances of this municipality are fairly good, it is to be hoped that they will take up these items in due course ; but the management of this municipality is not good. The municipality have recently got plans and estimates for a complete and satisfactory drainage scheme, but this has now been shelved.

Ahmedabad.—The municipality have recently got plans and estimates from Mr. Baldwin Latham for the completion of their drainage scheme, at a cost of about 16 lakhs (£107,000), exclusive of house-connections. The position of the proposed pumping station has had to be altered, and several details have had to be revised ; and the municipality are considering about the engagement of a special engineer, competent to revise the estimates,

and to superintend the work. They have applied for permission to raise a loan of 8 lakhs (about £53,000), and are prepared to proceed with the works as soon as Government have approved of the plans. The experiment of pumping some of the sewage to the lands under the Chandola tank has been successful. These fields are able to get plenty of irrigation water, and the sewage provides them with the necessary manure at a small cost. If the land in the vicinity of the existing small sewage farm can be got at a reasonable cost, it is proposed to give up the 300 acres got from Government about two years ago, at a distance of 3 miles from the city, as the cost of the rising main to that site will be heavy.

Kaira.—The water-supply of this town is a serious matter, as most of the wells, and the adjoining river Watrak for at least the worst portion of the year, only give brackish water. The Sanitary Engineer recently had a series of levels taken, and sketched out proposals for a scheme costing about £5,300. to supply 11,000 people, which is now under consideration by the local authorities.

Mehmadabad.—This town is 7 miles east of Kaira, and suffers under similar difficulties as to its water-supply. Similar measures were taken, and a proposal for a scheme costing about £4,700, to supply 9,000 people, is now under consideration of the local authorities.

Yeola.—As stated in the last year's report, this work is being carried out by the Public Works Department, and it is understood that the municipality paid the amount of the estimate into the Government account two years ago. The Executive Engineer states that not much progress has been made with the work, and that the indent for straight pipes and engines has only just gone in. The necessity for the water has been acknowledged repeatedly.

Ahmednagar.—The water-supply of this town is yearly becoming a more and more serious question. Lying, as it does, on a high tableland at about the boundaries of the N.E. and S.W. monsoons, it is liable to a recurring deficiency of rainfall. For some reason, the level of the subsoil water during the last 10 or 15 years has been steadily falling, affecting all the wells, and also the old aqueducts on which the city relies for its water. The only solution is the completion of the Kápurwádi tank, at a cost of about £10,000 for the work left undone at the end of the last famine. This tank lies over the upper portion of two of the old aqueducts, one of which will feed the city, and the other the cantonment and remount depôt. The water will percolate down into the aqueduct galleries, so that filter beds will be unnecessary. The municipality have prepared a scheme, at a cost of a little over two lakhs (about £18,500), for pumping and distributing this water under pressure throughout the town; and it is believed that the Executive Engineer similarly proposes to deal with the water of the other aqueduct for cantonments. The prevalence of enteric in the cantonments, and the recurrence of cholera in Ahmednagar, and in Bhingar, which adjoins the Sadar Bázár, points to the urgent necessity of doing away with the insanitary dipping wells and cisterns. The municipality has already spent a loan of a little over a lakh (about £7,000) on pumping and distributing water from one of the other aqueducts to about one-third of the town, and have incurred a further debt of about the same amount for plague expenses; their normal revenue is only about £4,700, and for the last two years it has been much less, so that probably the most they could do would be to carry out the pumping and distribution of the water to the rest of the town. From the increasing scarcity of subsoil water during the last two years, it is almost certain that, unless the next rains there are very favourable, there will have to be a move on the part of many of the 40,000 inhabitants of Ahmednagar, and of the 10,000 of Bhingar and the Sadar Bázár; and possibly also on the part of the troops, and of the large number of horses in the remount depôt. If Government could see their way to completing the tank, which has already been partially done as a famine work, it would solve what promises to become a very serious matter in the near future.

Kirkee.—The water-supply project for this cantonment is now nearly completed, and filtered water, under pressure, has been supplied to Government House, Ganesh Khind, and to most of the area to be served, for some months.

Poona.—Government have directed the Sanitary Engineer to get up a complete drainage scheme for this city; and one for the adjoining crowded Sadar and Sholápur Bázárs, which contain about one-fifth of the population of the adjoining city, the relative figures being about 22,400 and 127,000 respectively at present. It is hoped that this will be ready for consideration during the monsoon.

Wái.—The Executive Engineer carried out a series of levels, and drew out rough estimates for two alternative schemes, which have been practically shelved by the municipality.

Belgaum.—The military authorities have now declared themselves in favour of a combined water-supply project, which the municipality also are inclined to favour if they are relieved of their plague debt ; and it is to be hoped that Government in the Public Works Department will shortly examine the plans and estimates.

Akalkot.—This water-supply project is fast approaching completion, and it is hoped that the engines will be at work during this next hot season, *i.e.*, within less than a year of the final sanction. The work has been carried out under the superintendence of the Sanitary Board.

Sassoon Hospital, Poona.—The plans and estimates for the urgently required improvements to this building have been drawn out by the Sanitary Board in consultation with the Civil Surgeon, and have been submitted to Government.

Sholápur.—The municipality still continue the dangerous practice of relying on practically one engine for the water-supply of this important town ; and even this engine is now overworked. If it breaks down, even temporarily, the consequences will be disastrous. During the last two years the Executive Engineer has been getting up a drainage project, but he reports that the survey is not yet complete, and that he proposes to take up the elaboration of the project after July.

Sátára.—The question of Government taking over the management of the water-supply, in the interests of the inhabitants, both of the town and of cantonments, is still under discussion. The health of both communities would be benefited by such a measure, as the municipality are quite unable to supervise the miles of open channel from the Kás tank, so as to prevent pollution of the supply ; and yet the Municipal Commissioners seem to consider it derogatory to their dignity to allow the Government Executive Engineer to supervise this work for them, although his supervision would cost them nothing. If Government buys up the municipal rights, the provision of filter beds, and of a properly piped water-supply in the town, should be insisted on in place of the present insanitary dipping cisterns. From the nature of the site, a pressure of several hundred feet can probably be got in *two* places close to the town ; and with proper piping this might be utilised for electric light and power machinery, and still leave an ample head for the water-supply.

Miscellaneous.—The Board considered and advised upon the plans for the Lunatic Asylums at Nowpáda and Ratnágiri, and also advised on the preliminary proposals for the water-supply at Kundgal.

The Board again represented to Government the advisability of giving them executive, as well as consultative, powers ; so that they can both initiate and supervise the construction of important sanitary works of water-supply and drainage for municipalities, as the experience of past years proves that municipalities can only be induced to take up, and carry through, such measures by constant pressure and urging, and Executive Engineers have not the time for this work. We are more than ever convinced that it is only in this way that the construction of such urgently required works can be pushed on.

As regards the other municipalities mentioned in our last Report, we can only say that nothing whatever has been done regarding the points noticed therein.

ABSTRACT OF THE REPORT OF THE HEALTH OFFICER OF THE PORT OF BOMBAY FOR THE YEAR ENDING 31ST DECEMBER, 1898.

The following table gives a summary of the shipping and health of the Port of Bombay, and of the work in connection therewith, for the year ending 31st December, 1898 :—

Vessels, including Country Craft.	Number of Vessels Inspected.	Number of Persons Inspected, including Crew on Vessels.	Number of Vessels Disinfected.	Number of Persons Vaccinated.	Number of Persons segregated or rejected.	Diseases and Number of Cases of Each.								
						Plague.	Cholera.	Small-pox.	Measles.	Scarlatina.	Chicken-pox.	Enteric Fever.	Suspicious Fever.	Beri Beri.
Entered	18,081	285,743	20	150	4,277	5	—	8	3	3	5	1	3	2
Left	53,392	921,828	4	—	14,911	96	—	—	—	—	—	—	—	—
In Harbour during the year ...	25	—	25	—	—	17	5	—	1	—	5	—	—	—
Total	71,498	1,207,571	49	150	19,188	118	5	8	4	3	10	1	3	2
1897	72,898	1,313,117	69	161	42,552	169	30	11	4	9	—	1	—	—

It will be seen from the above table that 71,498 vessels of all sorts, with 1,207,571 crew and passengers, were examined during the year. The number includes every person who left Bombay by sea during the year, as well as those who arrived from the ports of Western India between Karáchi and Bhatkal, inclusive, between the dates of 1st January and 20th April, 1898. After the latter date, and up to the end of the year, arrivals from infected ports only were subjected to a medical examination.

The total number of plague cases detected during the year 1898 was 118.

The following table furnishes further particulars regarding vessels which entered the port during the year 1898 :—

Year.	Total Number of Steamers and square-rigged Vessels which entered Bombay Harbour from Ports other than Indian Ports.	Number of Passengers.	Total Number of Native Sailing Craft which entered Bombay Harbour from Ports other than Indian Ports.	Number of Passengers.	Total Number of Steamers and square-rigged Vessels which entered Bombay Harbour from Indian Ports.	Number of Passengers.	Total Number of Native Sailing Craft which entered Bombay Harbour from Indian Ports.	Number of Passengers.
a	*b*	*c*	*d*	*e*	*f*	*g*	*h*	*i*
1898	557	28,484	281	215	1,542	269,725	40,190	1,986
1897	551	27,605	204	191	1,583	289,154	36,831	2,217

There is no complete record kept of the crew of incoming vessels, and in the case of native sailing craft none of either crew or passengers ; hence the total number of persons who arrived by the vessels shown in the above table cannot be given. Of the 300,410 passengers shown in columns *c*, *e*, *g*, and *i*, 18,466 were troops, 1,342 pilgrims from Mecca, and the remaining 280,602 chiefly passengers from ports near Bombay.

The following table gives the number of ships which had infectious disease on board on or before entering the harbour :—

Class of Vessel.	Number of Ships.	Total Number of Crew and Passengers.	Diseases and Number of Cases of Each.								Number of Persons Vaccinated.
			Plague.	Small-pox.	Measles.	Scarlatina.	Chicken-pox.	Enteric Fever.	Beri Beri.	Suspicious Fever.	
Troopships	6	9,350	—	—	2	3	1	1	—	—	—
Pilgrim ships ...	2	526	—	6	—	—	—	—	—	—	139
Other vessels...	12	2,445	5	2	1	—	4	—	2	3	11
Total	20	12,321	5	8	3	3	5	1	2	3	150
1897	73	7,033	14	3	3	6	—	1	—	—	111

Vessels which became infected while in port are not shown in the above table, but are noticed in the table on page 186.

The cases of measles, scarlatina, chicken-pox, and enteric fever shown in the foregoing table as having occurred on board the troopships were landed and isolated in the Military Cantonment at Colába. The small-pox cases were removed to the Arthur Road Hospital on shore, and such of the persons amongst the crew and passengers as were found unprotected by previous vaccination or small-pox were vaccinated. The total number of persons thus vaccinated was 150. Out of the 12 other vessels referred to in the above table, 5 entered the port with a case of fully developed plague on board of each of them. Four of the vessels were Shepherd's coasting steamers from infected ports in close proximity to Bombay.

Table showing the number of vessels, crew and passengers examined on arrival at Bombay :—

Months.	Number of Vessels Inspected.			Number of Persons Inspected.							Number of Persons Segregated.		
				Passengers.		Crew.		Total.					
	Number of steam ships and square-rigged vessels.	Number of native sailing craft inspected.	Total.	Steamships and square-rigged vessels.	Country craft.	Steamships and square-rigged vessels.	Country craft.	Number of passengers.	Number of crew.	Number of crew and passengers.	Passengers.	Crew.	Number of crew and passengers.
January	181	4,249	4,430	11,311	335	3,427	28,097	11,646	31,524	43,170	2,986	—	2,986

Total ..	864	17,217	18,081	130,069	1,691	36,931	117,052	131,760	153,983	285,743	4,267	10	4,277

The examinations from 1st January, 1898, up to 20th April, 1898, include all arrivals from ports on Western India between Karáchi and Bhatkal inclusive, as all such ports were more or less plague-infected up to that date. From 21st April until the end

of the year only vessels arriving from infected Indian Ports and Hong Kong were examined before the issue of pratique.

The following table shows the number of outward vessels and their passengers and crew inspected month by month from 1st January to 31st December, 1898.

Months.	Number of Vessels Inspected.			Number of Persons Inspected.							Registered Number of Persons Rejected.				Total number of crew and passengers rejected.

During the year under report the total number of outward-bound vessels, crew and passengers examined was 53,392, 481,982, and 439,846 respectively. Out of the 53,392 vessels shown in the foregoing table, 381 vessels left with 30,991 crew and 26,997 passengers for Aden, Red Sea, and Europe; 402 vessels, with a total of 30,742 crew and 12,693 passengers, for ports out of India other than Aden, Red Sea, and Europe, and the remaining 52,609 vessels, with 430,249 crew and 399,886 passengers, for Indian ports, including Burma. Since the 1st September, 1898, the inspection of the crew and passengers of outward-bound vessels which sailed to ports other than Indian ports has been made by day on shore prior to their embarkation, as directed by the Venice Sanitary Convention. The ship's company was again inspected on board before the issue of a Bill of Health immediately before departure from this port. The Bill of Health form B., prescribed by the Government of India in 1890, and issued to vessels sailing for foreign ports, was accordingly revised by the addition of the following words in manuscript after "passengers or crew" in the last line of the 1st clause of the Bill, *viz.*, "who have been examined by day on shore before embarkation and found free from plague."

During the year the sanitary condition of all outward-bound vessels was well looked after by the commanders and agents. The forecastle was painted or limewashed before departure. The inside of the crew's boxes was similarly dealt with, and the clothing and bedding of the crew were exposed to the sun. Bilges in native craft were generally found clean, and were carefully attended to. The holds of all vessels in ballast were thoroughly cleaned, and in most cases limewashed or disinfected with a solution of carbolic acid.

Arrangements were made with the P. & O. Company by which the bedding and clothing of the native crew on ships bound to Europe was disinfected.

The overcrowding of crew's quarters, which was brought to the notice of Government in previous reports, was not marked during the year under report. During the year 1897

the overflow pipes from the water tanks on board of some vessels were found to discharge directly into the bilges. This insanitary state of affairs, noticed during the year 1897, was observed during the past year. During the months of November and December the water tanks of all vessels were examined, and out of 163 ocean-going steamers 14 were found to have the overflow pipes from the water tanks leading into the trough in connection with the bilges.

Infectious Disease on Vessels in the Harbour.—The following table includes all steamers, square-rigged vessels and native craft which became infected while lying in the port, and is inclusive of those given in the first table on page 184, which became infected while at sea, or whose passengers developed plague after arrival :—

Months.	STEAMERS.											BUGGALOWS, TONIES, PROWS, STEAM LAUNCH, &C.										TOTAL NUMBER OF CASES OF INFECTIOUS DISEASE IN THE BOMBAY HARBOUR.

All the above vessels, including those in the first table on page 184, were thoroughly disinfected in accordance with the rules laid down in the Venice Sanitary Convention.

Disinfection of Ships and General Health of the Shipping.—During the year 1898 the total number of infected vessels of all sorts disinfected under the personal supervision of the Port Health Officer or his staff, assisted by the Water Police, was 49. The Resident Transport Officer arranged for carrying out the Port Health Officer's recommendations for the disinfection of transports in which cases of infectious diseases occurred.

The general health of the harbour population was fairly satisfactory during the year. The various hospitals in the city admitted, during that time, 814 persons connected with the shipping. This number of admission is exclusive of plague. Of these, the St. George Hospital admitted 485 Europeans, of whom 18 died ; the Jamsetji Jijibhoy 54 natives, of whom three died ; and the Gokuldas Tejpal 275 natives, of whom 19 died.

No deaths occurred from the effects of cleaning bilges of ships during the year, but the Coroner of Bombay held one inquest on the body of a lad who had died from suffocation while cleaning an engine-well on board the S.S. "Dean," and 13 inquests on persons who had met with their deaths from accident on board the ships in the harbour and in the docks.

Red Sea Pilgrim Traffic.—Owing to the existence of plague in Bombay, the pilgrim traffic between the Indian ports and Jeddah was stopped during the year 1898. Accordingly no vessels with Mecca pilgrims left this port for Jeddah during the year, but 1,342 pilgrims returned from Jeddah *viâ* Aden and other routes. The baggage of all returning pilgrims was disinfected by the Port Health Officer, under the orders of the Government of India. The pilgrims were not allowed into the town, but were sent direct from the ship to their homes in batches by rail, at the expense of Government.

Emigration Traffic.—During the year four ships left Bombay with emigrants for the Uganda Railway and Seychelles. The emigration traffic was closed from Bombay on

account of plague, and no vessels with emigrants sailed after the 26th February, 1898, from the port of Bombay, with the exception of the S.S. "Patna," which left the port on 9th October, 1898, with 274 emigrants for the Seychelles Government under Government of India Notification, No. 1,999—12-26, dated 23rd September, 1898.

Sanitary State of the Harbour and Foreshore.—No remarks are made on the state of the harbour and foreshore as they were not inspected during the year owing to pressure of work.

Plague.

Owing to a marked recrudescence of the plague in January an exodus set in, and 30,878 more people left Bombay by sea than arrived during that month. They were chiefly mill-hands and labourers who had their homes along the coast in close proximity to Bombay. In order to prevent the spread of plague to the coast ports Government directed that in addition to the inspection before leaving Bombay the people were to be inspected a second time at the port of arrival. Native craft were prohibited from taking native passengers, so that the inspections at the coast ports could be carried out at the places where steamers called.

It has been our experience that in almost all cases of plague a slight increase of temperature exists for a few days before the more marked signs and symptoms show themselves. It is for this reason that the most accurate means should be taken to obtain the correct temperature of suspected individuals at the examinations. Temperatures have been taken in the axilla since March with half-minute thermometers. These temperatures are not as a rule accurate. If they are taken in the early morning the skin of the natives has been cooled by exposure to the air, and if they are taken during the heat of the day the skin is also cooled by evaporation owing to perspiration. It is for these reasons that a slight rise of temperature in a native cannot under the circumstances under which they are examined by us be detected unless it is taken in the mouth. This had been the custom at one time. Every possible precaution had been taken to remove sanitary or sentimental objections. The thermometers were washed in carbolic acid lotion, and afterwards in a stream of water from a tap. Each caste had its own set of thermometers, and temperatures were taken by one of their own caste people, but the system had to be abandoned owing to caste prejudices. At our inspections during the year we came across instances where passengers suffering from a rise of temperature tried to reduce it immediately before the examination by wetting their bodies with water, sucking ice, or taking doses of phenacetine.

Owing to the diminution of plague along the coast ports near Bombay, inward sea inspections from such places were suspended on 20th April, and only vessels coming from infected ports were examined.

When the third marked epidemic of plague in Bombay commenced towards the end of the year, arrangements were made with the P. & O. Company for the disinfection of all the clothing and bedding of the native crew prior to sailing. This disinfection has now been extended to the clothing and bedding of all native crews bound to any port out of India, and is working satisfactorily.

The newspapers reported cases of plague from Bombay at foreign ports from time to time, but subsequent enquiry in almost all cases proved that they were not cases of plague. They were generally natives who had suffered from chronic enlarged glands, and who had been so unfortunate as to be suffering from an attack of malarial or other fever at the time the ship arrived in a foreign port. In order to avoid such cases being classed as plague, we insist on the passenger providing himself with a medical certificate which he can produce at a foreign port. In the case of one of the crew full particulars are entered in the official log book, so that the captain may be able to produce it as evidence to show that the disease is not due to plague. This is done with a view to save the vessel and passengers unnecessary restrictions at ports outside of India.

The P. & O. Steamship "Caledonia" was reported to have had plague at Suez in November last. The following is the history :—

At our examination on the 19th November, 1898, we found a man with fever. He was sent for observation, and the doctor in charge of the hospital reported that it was plague. The information was telegraphed to Suez by Government, and on the arrival of the vessel at that port two native crew suffering from fever were removed from the ship. Reuter telegraphed as an item of news that they

were plague cases. We wrote to Egypt for details of the cases, and at the same time asked for a list of plague cases imported from Bombay during the year 1898. The President of the Quarantine Board replied that neither of the men removed from the "Caledonia" could be considered to have developed plague, and further, that no genuine case of plague had been imported from Bombay during the year 1898.

Another case of plague was reported in the newspapers to have been imported into Ceylon from Bombay. This turned out to be a man with chronic enlarged glands. He had been a resident in Bombay, but left by rail for Tuticorin, where he embarked for Colombo. The medical officer at Colombo wrote to say that the man was not suffering from plague.

Efforts were made by certain newspapers to trace the outbreak of plague in Madagascar to Bombay. At first it was stated that it had been brought by native craft, but this theory was given up. It was then stated that it had been imported by a rice-laden steamer from Bombay. The last steamer which left Bombay for ports in Madagascar, either directly or by first calling at an intermediate port, sailed on the 9th August, 1897. She had a doctor on board. As far as we know, plague broke out in Tamatave in November or December, 1898, that is fifteen months after the last steamer left Bombay for Madagascar.

During the year 17 cases of plague were found on vessels and native craft in the harbour. Besides these, 96 cases were prevented from sailing on vessels leaving the port, and 5 were found on vessels coming from infected ports close to Bombay.

A special sanitary police force was found necessary to assist the port health staff in carrying out the provisions of the Venice Convention. Government, therefore, sanctioned 12 European and 50 native police for such work, and placed them under the orders of the Port Health Officer.

ABSTRACT OF THE REPORT OF THE CALCUTTA MUNICIPALITY FOR 1898-99.

(W. R. Bright, Esq., Chairman.)

Review of the Period 1888–1899.

When the system of Government of the town of Calcutta was about to be changed in 1888 by the introduction of the present Act, the Commissioners, in the Annual Report for the year 1887–88, gave a short history of the principal works carried out and the principal reforms effected during their tenure of office.

Eleven years have passed, and the constitution of the Corporation is again on the eve of important changes. The present time would therefore appear to be one when the Commissioners should give an account of their stewardship. They have met with much criticism in the past, and as they believe that their critics have been in a great measure ignorant of the real extent of the important works carried out by them, it seems only just that a plain statement of facts should be given of the work actually done. The Commissioners are fully aware that there is much need for improvement, and had they unlimited funds at their disposal, they would have been able to do far more than they have done. But they maintain now, as they maintained in 1888, that they have effected a large number of improvements, that these improvements have been wisely chosen, and that they have arranged for the expenditure of as large a sum of money as they could possibly have done in view of the financial position of the Corporation.

Putting aside the constitutional changes which were introduced by the present Municipal Act, the most important feature of the past 11 years has been the inclusion of the Suburban and Added Areas in the Town Proper. In the Annual Report for 1885–86 the late Sir Henry Harrison wrote as follows :—

> Turning now to the new area to be added to the town, hardly a rupee of capital has been expended upon it, and such expenditure is quite as urgently requisite as it was 20 years ago in the case of the town.
>
> 1st.—The water-supply of the town should be extended so as to give reasonable facilities for obtaining pure water for domestic purposes to all residents in the suburbs.
>
> 2nd.—Some system of underground drainage should be introduced, and even if it is not on nearly so expensive a scale as that of the town, it must cost at the best a large sum of money.
>
> 3rd.—The new area is intersected with tanks, many of them filled with most unwholesome water, the number of which far exceeds that in the town 10 years ago. The opinion that filling up tanks with refuse is dangerous seems to be daily gaining ground, and it is very probable that before long it will be prohibited ; in that case considerable outlay for the conveyance of earth from a distance will be requisite.
>
> 4th.—The condition of the Mahomedan burial-grounds is such that it is imperatively necessary to take up land at an estimated cost of 1½ lacs (£10,000), in order to enlarge them and allow a suitable interval between the use of the same ground for a second interment. It is found that at present the same land has to be used over and over again, after three years in the less crowded, two in some of the others, and scarcely more than one year in the most crowded cemeteries. A proposal is already before Government to appoint a Mahomedan Burial Board to supervise and control the Mahomedan cemeteries, the condition of which is at present such a serious menace to the health of the localities in which they are situated, and if this proposal is adopted, it may be taken for certain that their first application must be for a liberal outlay of money, probably two lacs (£13,300), which ought to return an income sufficient to pay the interest and up-keep of the cemeteries. Will the Government give the money, or will it refer the board to the municipality ?
>
> 5th.—The conservancy of suburbs is at present managed by the contract system, and it is understood that it does not give satisfaction. It will be at least desirable to incur a considerable outlay in building Gowkhanahs and purchasing conservancy carts and cattle ; possibly also a railway extension may be necessary, so as to remove the bulk of the refuse more easily to a distance.
>
> 6th.—A proper *dhobikhana*, as at Bombay, where dhobees will be provided with pure water and other cleanly surroundings will also be a great desideratum. This should pay its own way easily, but it will require capital at the outset.
>
> It would be easy to add to the list, but the above outline is sufficient to show that a considerable outlay in the form of capital is a *sine quâ non* to the success of the new corporation, the return being partly in the form of a water-rate, partly of a direct income, partly in the enhanced value of property.

It is interesting and instructive to note how far these needs have been supplied :—

1st.—As regards the supply of filtered water to the suburbs, the history of the past 11 years is one of continuous progress. The actual scheme for the extension of the filtered water supply was completed in 1888-89, but much has since been done to increase and improve the supply of the suburbs. A new pumping station has been erected at Bhowanipur, with reservoir, engines, engine-house and quarters, &c., complete. The cost of this was :—

	£
Cost of land acquired	19,287
Cost of reservoir to hold 3 million gallons	8,874
Engines and boilers	10,350
Engine-house and boiler-house, quarters, &c.	9,446
	47,957
Then a pipe-bridge was constructed over Tolly's Nullah at a cost of	3,590
And roads were constructed within the pumping station compound at a cost of	473
Total	52,020

No less than 132·03 miles of mains and services have been constructed at a cost (including alterations to mains and piping) of Rs. 10,30,562. This makes a total expenditure of Rs. 18,10,859, and to this should be added part of the expenditure incurred in increasing the pumping power of the town. As a result of this large expenditure the added and suburban area is now supplied throughout with an excellent supply of filtered water. The first need of the added area has therefore been met.

The second crying need of this area was declared to be the provision of a scheme of underground drainage. This question and that of improving the drainage outfall of the town area was gone into most carefully by the corporation. After the opinion of experts had been taken, a joint report was drawn up by Messrs. Kimber and Hughes, and after this had been sanctioned, the work was split up into three contracts, numbered II., III. and IV. Of these III. and IV. relate almost exclusively to the added area. The estimate of the former was nearly 20 lakhs (£133,000), while the final estimate of the latter exceeds six lakhs. The latter is practically complete, while the former is under construction. It will probably take nearly three years more to complete the whole scheme in all its details, but the work has made good progress, and it is hoped that the scheme when finally carried out will be entirely successful. Due action has, therefore, been taken to provide for the needs of the suburban area in this respect.

The third point, upon which improvement was said to be required, was to fill up the filthy tanks which are so numerous in the suburbs. It has been found impossible to deal adequately with this very large question, but the provision of filtered water has done away with all necessity for using the water of these filthy tanks for drinking. A number of tanks have no doubt been filled up, but the total number is so large that very little impression has been made upon it.

The next point upon which improvement was required was stated to be the provision of proper Mahomedan burial-grounds. Here again this need has been to a certain extent met, as the corporation two years ago provided a fine cemetery at Gobra, which has been filled up much faster than was expected, and the enlargement of which has now been sanctioned. The total cost amounts to £2,372. There still remains the provision of a cemetery in Maniktolla, but it has been found to be most difficult to select a suitable site, and the matter is still under consideration. The Mahomedan Burial Board, which is in charge of cemeteries, has no income of its own except a grant from Government sufficient to meet the office expenditure, and the only body which is called upon to pay the expenses of providing these burial-grounds is the corporation, which, in the face of the large contracts entered into for the extension of unfiltered water-supply and the improvement of the sewage system, has very little money to spare.

The next point upon which improvement was declared to be necessary was in the conservancy of the suburbs which was managed by the contract system. Here again much has been done to improve matters. An incinerator has been erected at Goragatcha, at a cost of £3,934, which deals successfully with the conservancy of

wards 23, 24 and 25. The contract system is now in force only in wards 23, 24 and 25 for removal of refuse, but for sullage and trade refuse it is in force in wards 19 to 25. But it is in the matter of the disposal of night-soil that great improvements have been effected, and the trenching system has been entirely abandoned owing to the construction of temporary sewage depôts at Hazra Road and Budge-Budge, where the night-soil is emptied into the sewers and then pumped into the large Circular Road Sewer at Bhowanipur. This scheme necessitated an expenditure of £26,222.

The last improvement suggested by Sir Henry Harrison was the establishment of a *dhobikhana*. Here again, the need has been met. A municipal *dhobikhana* was erected at a cost of £3,398, including the cost of acquisition of land. The yearly income and expenditure have been as follows :—

Year.	Income.	Expenditure.	
	£	£	
1896-97	26	3	Only for a portion of the year.
1897-98	171	46	
1898-99	169	46	

so that it is yielding a net return of 3·2 per cent. on the capital expended on its construction.

The foregoing paragraphs will have shown that, since the added area has been included, the corporation has either fully or partially met all the needs of the added area which were declared to be most pressing. They have given a full supply of filtered water, they are constructing a complete system of sewers, they have established an incinerator to dispose of the refuse, and have changed the system of the disposal of night-soil, while they have instituted a municipal *dhobikhana*.

But they have done much more than this, for they have extended the unfiltered water-supply to the south added area, and have opened out a number of very fine roads. On the former they have expended £53,237 (including 41·75 miles of mains, branches, and hydrants). On the latter they have expended—

	£
Badiapara Road	22,543
Landsdowne Road	21,814
Kalighat Bridge to Russa Road	8,232
Judge's Court Road	847
Chetla New Road	5,374
	58,810

It would be wearisome to go into the improvements effected in the suburbs at any greater length. Under the Act the corporation is bound to spend a sum of not less than £20,000 a year on the improvement of the suburbs. After taking into consideration certain capital expenditure the interest upon which according to the opinion of the Advocate-General is justly debitable to this fund, the amount of interest now payable for works benefiting the suburbs at present exceeds £20,000, which was the minimum to be spent yearly from revenue upon the suburbs.

Leaving the financial side of the question, it is most important to see whether the works carried out for the improvement of the suburbs have had a beneficial effect upon the health and well-being of the people of those parts. Taking the two diseases fever and cholera as those which we might expect to be affected by the extension of the filtered water-supply, the results are most satisfactory. In the two quinquennial periods before the amalgamation the five yearly averages of deaths in the suburbs from fever alone amounted to 4,657 in the first, and 3,754 in the second period. Since the amalgamation the five yearly averages have been 2,959 and 3,424 respectively. The increase in the second period is coincident with an even greater increase in the town. Part of it is no doubt due to increase in population, as the figures are calculated upon the census figures of 1891.

As regards cholera, however, the improvement is much more marked. Taking the six years previous to the amalgamation there were only two years in which the total number of deaths from this cause was less than 2,000 per year, and the lowest number of deaths recorded from this disease was 1,641 in 1885-86. The average annual number of deaths

from this cause during this period was 2,101. From the date of the amalgamation onwards there have been only three years in which the total number of deaths exceeded 1,000, while the quinquennial averages have been 918 for the first and 692 for the second period. No words are needed to show how great an improvement has been effected in this case by the works carried out since the amalgamation. Even now, however, the rates per mille are higher in the suburbs than in the town, and this is probably attributable to the vastly larger number of tanks still in existence there.

As regards fever, the decrease observable is the more satisfactory as it might well have been expected that the provision of an ample filtered water-supply without the necessary *pukka* drainage system to carry off the sullage and waste water might have resulted in great water-logging of the soil and a consequent increase in malaria. With the completion of the new drainage system for the suburbs it may be confidently expected that the death-rate from fever will diminish, while the construction of a drainage system in the fringe area will, it is hoped, have the same effect for that part of the town.

Turning now to the administration of the town as a whole, the history of the last 10 years is a record of large sums yearly spent on improvements.

The loans raised during that period have amounted to over £1,000,000.

An additional loan of 4 lakhs (about £27,000) was also raised for plague expenditure, the date of the debentures being the 1st May current; but as this loan was for an exceptional cause, it has not been included in the above amount, which is of sums raised for the improvement of the town and suburbs.

The total expenditure on improvements from 1889–90 up to the beginning of the past year has been:—

	£
From Capital	1,004,744
From Revenue	110,679
Or a total of	1,115,423

What then has been the net result of the expenditure under the main heads? As regards drainage a large amount has been expended on the unfinished projects for the suburban area, as well as for the town outfall. As regards the town proper, in 1888–89 there were 37·3 miles of brick and 140·3 miles of pipe sewers. There are now 42·71 miles of the former and 150·24 of the latter. At the same time there has been great improvement in the number of times the sewers are cleaned and flushed. In 1888–89, 386·28 miles of brick and 3,514·27 miles of pipe sewers were flushed and cleaned, while in 1898–99, 852·20 miles of brick and 9,066·09 miles of pipe sewers were similarly treated. That is to say, that while in 1888–89 each brick sewer was cleaned on an average 10 times and each pipe sewer 25 times, in 1898–99 each brick sewer was cleaned on an average 20, and each pipe sewer 60 times. Much importance is rightly attached to the periodical cleansing of the sewers, and the increase noted above is a real improvement.

Provision is being made this year to lay unfiltered water pipes to the summits of the sewers which we have hitherto been unable to flush owing to their position, and arrangements are also being made for maintaining the pressure of the unfiltered supply throughout the hours of the day and practically the whole of the night. It will then be possible to greatly improve our flushing. Already automatic flushing-chambers have been fixed in several places, and these are being yearly increased in number.

The next class of work to be noted upon is roads. In 1888–89 the total length of roads in the town was 184·3 miles, including 34·9 paths over sewered ditches. The total length in 1898–99 is 201·1 miles, of which 35 miles are paths over sewered ditches. There has therefore been an increase of 27 miles of roads in the town, and while the expenditure or upkeep in 1888–89 amounted to £11,469, the amount sanctioned for the year under review was £16,000.

In dealing with the expenditure on the suburbs I have noted the new roads which have been constructed there. In the town proper the cost of land is so great that it is impossible to fix the money for making large roads. One very fine road has been made—the Harrison Road, but the actual expense of this after giving credit for sale of surplus land and taking credit for the increased assessment on the new frontages has never been ascertained. The information would be of great value, but the calculations would be extremely difficult and complicated, and the assessor, who is the only officer who could make them, is far too hard worked to be able to spare the necessary time.

The next head under which very large sums have been expended has been on the improvement of the water-supply of the town and suburbs. These briefly speaking comprise:—

(*a.*) The increase in the supply of filtered water.—In 1889–90 the average daily supply rose to 16,000,000 gallons. It is now 20,684,106.

(*b.*) The extension of the filtered water supply to the suburbs.—This has already been fully noted upon.

(*c.*) The increase in the supply of unfiltered water in the town.—In 1888–89 the daily average was 2,881,842. In 1898–99 it was 4,778,899.

(*d.*) The extension of the supply of unfiltered water to the south suburban area.—The works have been completed, and the pipes are being tested.

The result is that while in 1888–89 there were 241 streets provided with unfiltered and 601 with filtered water, in 1898–99 there were 393 streets connected with unfiltered and 1,039 supplied with filtered water.

The great task now before the corporation is to devise means for—(*a*) maintaining a continuous supply of water, and (*b*) checking the waste which undoubtedly exists, and it is in this direction that our efforts will have to be directed in the future. Both problems are difficult, but there can be no doubt that they are capable of solution, and that their solution would result in economy.

The next major head which requires special mention is that of Bustee and Town Improvement. Under the law the Commissioners are bound to spend on the completion and extension of the Calcutta Drainage Works and the opening out and improvement of bustees a sum of not less than two lakhs (£13,300) a year, to be raised by loan, and it is of course obvious that, as the sums which are spent on drainage increase, those available for the improvement of bustees must naturally decrease. Already about 33 lakhs of rupees (£110,000) have been expended on the improvement of the drainage. But in addition to this the corporation has spent more than 5 lakhs of rupees (£33,000) in opening out bustees during the period under review. Projects which will involve another 5 lakhs of rupees have been sanctioned, and are only kept in abeyance owing to the very large sums which are being expended on drainage works, and many other projects are under consideration. The Commissioners are fully alive to the necessity for improving the bustees of the town and suburbs, but they have been compelled of late years to decrease their expenditure in this line in view of the heavy liabilities which they have incurred in their large contracts for the improvement of the drainage and sewerage system.

So much attention has been drawn of recent years to the conservancy of the town that it seems necessary to devote a short paragraph to this subject. The first point to which attention is naturally drawn is the question of expenditure. In 1889–90, the first year of the amalgamation, the expenditure was £37,926 in round numbers. In 1898–99 it had risen to £43,372. The true test, however, of the efficiency of the conservancy establishment is the amount of refuse deposited at the Salt-water Lakes.

The following figures will show how greatly the amount thus deposited has increased: —

	Waggon-loads of Town Refuse.		Waggon-loads of Town Refuse.
1889–90	21,018	1894–95	26,599
1890-91	21,899	1895–96	28,043
1891–92	23,048	1896–97	30,347
1892–93	23,956	1897–98	31,725
1893–94	25,829	1898–99	30,508

Some small part of this increase is due to the fact that the refuse of certain wards which used to be disposed of at the municipal dumping-ground is now sent to the square-mile, but this only represents a comparatively small fraction of the increase. The increase in population would, of course, naturally cause an increase, but even this would not account for an advance of over 40 per cent. this year and over 50 per cent. last year over the figures of 1889–90. As each waggon is said to contain 10 tons, the amount of refuse now removed has reached the very large figure of about 300,000 tons a year.

It is perhaps unnecessary to go at greater length into the history of the improvements effected during the past 10 years. To enter into them in greater detail would be to expand this chapter to an inordinate length. Enough has, however, been given to prove

that the history of the past 10 years has been one of continuous improvement. It is important, however, to notice at some length the financial side of the question. The Budget estimate of 1889–90 provided for an income of—

£		
180,775	...	from the General Fund
21,467	...	do. Sewage-rate.
63,134	...	do. Water-rate.
21,334	...	do. Lighting-rate Fund.
286,710		

The Budget estimate for the present year provides for an income of—

£	
213,527	... General Fund.
27,316	... Sewage-rate.
91,762	... Water-rate.
32,369	... Lighting Fund.
364,974	

The rate of taxation in both years is the same. The increase in the estimated income is due entirely to the increase in the valuation of the city. In 1889–90 the 1 per cent. rate was estimated at £11,598. In 1899–1900 it is estimated at £14,000.

At first sight it might appear that the large increase which has taken place may fairly warrant largely increased expenditure on the current needs of the town, but this is not so. In 1889–90 the estimate for interest on loans was £59,496 and that for sinking fund £23,111, or a total of £82,607. In the current year's Budget the estimated expenditure is £137,576, an increase of £54,967 in round numbers, against an increase in estimated revenue of about £78,267. It is therefore clear that while the increase in interest and sinking fund charges is still met by the increase in revenue due to the rise in valuation, there is no margin for greatly increased expenditure.

Suburban statutory 3 lakhs Accounts.—It will appear from the following statement that the corporation, while under an obligation to expend £200,000 on the suburbs during the last 10 years at £20,000 a year, have actually spent £12,560 more than this amount :—

		£	
Interest and contribution on water-supply capital expenditure up to 1898-99		14,762	
Interest on drainage and miscellaneous capital expenditure during 1898–99		6,985	
Improvements from revenue account	2,002		
Less amount excess shown in 1895–96 and 1896–97	64		
		1,938	
Cost of new lamps		61	
			23,746
Add expenditure up to 1897–98			188,814
Total expenditure up to 1898–99			212,560

Plague in Calcutta.—The year under review has been rendered memorable by the advent of plague. Although this disease had obtained a firm footing in the Western Presidency during the previous two years, Calcutta had been hitherto immune from its attack. Unfortunately this immunity did not continue during the past year, though happily in neither of the two outbreaks did the plague assume the excessively virulent epidemic character which characterised it in Bombay.

During both the outbreaks the plague operations were under the management of the Chairman. Up to the 23rd July the Health Officer was in direct charge, but on that date he made over charge to Major W. Bannerman, I.M.S. This officer was relieved by Dr. Pettifer, who remained in charge for a short time and then made over charge to Major Green, I.M.S., who remained in charge for the remainder of the year.

The first information of the approach of plague was given by the death of a number of rats on the 15th April, 1898. This was quickly followed by the report of a plague case on the 17th April. Other cases speedily followed, and on the 30th April an official announcement that plague existed in the town was made in the Bengal Council. The disease continued until the end of the rains, though most fortunately it never developed into a severe outbreak. On the 10th October the town was declared free from plague.

As was only to be expected, the declaration of plague as existent in the town led to a considerable amount of panic. Exaggerated ideas of the measures which would be taken were rife, and a very extensive exodus resulted. The measures taken to deal with this epidemic were :—

(*a.*) The establishment of public hospitals. Three were provided in addition to the old one at Manicktolla, which had been constructed in 1896, and had never been used. The new hospitals were established in—

(1.) Manicktolla, where a fine two-storied house was rented, and thatched huts constructed in the compound.

(2.) Marcus Square, where a number of sheds roofed with corrugated iron were set up.

(3.) Budge-Budge Road, where a fine house was rented and furnished as a hospital, thatched huts having been constructed in the compound.

(*b.*) Provision of ward hospitals.

(*c.*) Provision of caste hospitals.

These two classes of hospitals were equipped and arranged for by private munificence or voluntary subscription.

The liberality with which donations (in many cases large ones) were given by the citizens was most remarkable.

(*d.*) Licensing of family hospitals.

(*e.*) Segregation of sick and their careful nursing and treatment in public hospital.

(*f.*) Segregation of "contacts." House-to-house enquiries to discover cases of plague and suspicious cases.

(*g.*) Disinfection of houses, clothing, &c.

(*h.*) Inoculation.

(*i.*) Establishment of vigilance committee in each ward.

For administrative purposes the town was split up into districts, each under the charge of medical officers, most of whom had been sent out by the Secretary of State.

At first considerable opposition was met with, ambulance parties were attacked, and in one case so serious an attack was made upon a medical officer that he had to use his revolver in self-defence.

With a view to obtaining early information of cases of plague, vigilance committees were established by the commissioners in each ward. These consisted of two elected and one nominated commissioners, assisted by the leading ones. Their duties were to carefully inspect the ward, and to report as regards unusual dirt, faulty drains or sanitation, and cases of suspicious sickness or deaths, and to make suggestions for other sanitary improvements. Military officers were appointed to assist them. These committees mostly worked well, but had many difficulties to contend with.

Fortunately this attack never assumed the proportions of a severe epidemic, and when it died away in October, and Calcutta was declared to be free, there was some ground for hoping that the disease would not recur. Unhappily this proved not to be the case. Occasional cases were reported during the cold weather, and in consequence of their increasing numbers the plague rules were reimposed by Government Order No. 1,145-Medical, dated the 24th February, 1899.

There was, however, a most notable change of policy. For the first time it was resolved that, while every effort should be made to induce plague patients to resort either to the public or the ward and caste hospitals, no one should be removed against his will, and that those who were unwilling to go to hospital should be treated at their own houses, arrangements being made as far as possible to adapt the house for the purposes of a private isolation hospital. The conciliatory character of this measure greatly reassured the mind of the public, and although plague assumed an epidemic form of far greater intensity than in the previous year, the exodus of people was unimportant, and there was hardly any dislocation of trade.

On the other hand, so far as can be seen, the measures thus adopted have had no untoward effects, and the disease fell away to a vanishing point with the advent of the rains.

After the reimposition of the rules the number of plague deaths reported increased rapidly. The disease reached its maximum in April, and then gradually decreased, but between the 25th February and 1st July no fewer than 1,200 deaths had been reported from this cause alone, and there can be no doubt whatever that in spite of the conciliatory character of the measures adopted a large number of cases were concealed.

The change in the policy pursued resulted in a great change in the attitude of the people. While great opposition had been experienced during the first outbreak, practically nothing of the kind was encountered during the second and far more serious epidemic, and this change in the attitude of the people rendered work during the second outbreak much easier.

During this period the town was divided at first into four and afterwards into five districts, each in charge of a medical officer, and each equipped with a sufficient staff of medical inspectors and disinfecting gangs.

Much attention was paid to promptness in disinfection, and, as actual experience increased, it was found possible to secure extremely prompt measures in each case of reported plague.

It is unneccessary in a short *résumé* of this kind to go at greater length into the details of the administration. It is a matter for great congratulation that the milder and more conciliatory policy adopted in the second epidemic seems to have been quite as successful as the earlier and more drastic methods, while the almost entire absence of any recurrence of the disease in rooms which had once been disinfected is a striking testimony to the value of this measure.

Undoubtedly many cases were concealed, but it cannot be disputed that far more cases would have been kept back if more drastic methods had been adopted.

Moreover, it was a matter of the greatest importance that the general trade and business of the town should not be upset, as would inevitably have been the case if more drastic measures had been used. It may be safely stated that the result of the more conciliatory policy has been most satisfactory. While it has in no way tended to increase the epidemic, it has allayed panic and has enabled the ordinary business of the town to go on with little hindrance.

The advent of these two epidemics has, of course, thrown a great additional burden both upon the Commissioners and upon the Chairman. Upon the Commissioners, because it was by their efforts that vigilance committees were organised and maintained and ward hospitals started ; upon the Chairman, because, in addition to the heavy burden of responsibility which the ordinary work of the corporation entails, he had to undertake the supervision and management of the staff and methods necessary to deal with a severe epidemic. Upon the corporation too the burden has fallen heavily, as they have had to provide the funds for all the necessary arrangements and establishment. For this purpose they contracted a loan of 4 lakhs (£26,700), and further sums would have been required had not the Government come to their aid with the munificent grant of 3½ lakhs (£23,300).

It is a matter for great thankfulness that, in spite of the visitation of plague during the year, no serious interruption has been caused for any length of time in the great general municipal administration of the town. The collection of rates has been nearly up to the usual standard, while the collection of arrears has considerably exceeded the figures of previous years. In one department, however, serious difficulties were met with during the year. This was the Conservancy Derartment, and here great difficulties were caused by the strike and flight of a number of the carters.

Water Works.—The extension of filtered water mains and services during the year under report amount to ·56 mile, namely, ·29 mile in the added area, and ·27 mile in town area. Besides the above, 5 standposts have been fixed. The total mileage of filtered pipes on the 31st March, 1899, amounted to 315·05 miles. The number of premises connected during the year aggregated 568, raising the total number to 28,343. 1,992 standposts, 8 drinking fountains, 224 ground hydrants, 13 urinals, 84 bathing platforms, and 93 cattle drinking troughs are connected with the filtered system. The average daily consumption of filtered water for the year was 20,684,393, against 20,638,212 gallons in 1897–98.

The daily unfiltered supply was 4,778,899 gallons, and the consumption per head of the population (436,393) a day amounted to 10·95 gallons. The total length of unfiltered water mains and services in town area on the 31st March, 1899, amounted to 104·26 miles.

Drainage and General Construction.—During the year 2·66 miles of pipe sewers were reconstructed to new specification and 3·98 miles of brick sewers were repaired. Thirty sewer man-holes, 24 sewer lamp-holes, 49 gully-pits and 59 flushing chambers fitted with automatic flushing syphons were constructed. The public sewers, excluding 9·46 miles of bustee sewers, now measure 200·630 miles. These figures refer only to the sewers now in operation and do not include the work completed under the big contracts. Of works of public convenience, 3 double-seated urinals with white-glazed tiles have been constructed and brought into use. Four bathing platforms, four night-soil depôts, five latrines and six urinals have been thoroughly repaired. Two hackney-carriage stands paved with Indian patent stone have been constructed. 308,110 tons of refuse were conveyed by the municipal railway to the square-mile during the year. In addition to this, 16,865 tons of road metal and building material were hauled from the store depôt at Baug Bazar and unloaded at the various sub-depôts in Circular Road.

House Drainage.—Three hundred and twenty premises were connected with the public sewers during the year, bringing the total up to 30,168. The drains of 5,879 premises were examined for structural defects, and in 2,065 instances, or 35 per cent., these were discovered and notices specifying these defects were issued. The drains of 9,878 premises were re-inspected, 20,399 were specially inspected on account of the outbreak of the plague, and in 6,882 instances drains more or less obstructed were cleaned out, flushed, and disinfected. Sanction was accorded to the connection of 410 privies with the public sewers.

Roads.—The total length of roads on 31st March, 1899, was 331 miles, 6 furlongs, and 296 feet, of which 104 miles, 3 furlongs, 447 feet are stone-metalled, and 165 miles, 4 furlongs, and 620 feet are brick-metalled.

Health of the Town.—It is satisfactory to note that the year under review has been a healthy one, the death-rate being the lowest since 1893. The mortality from fevers and cholera was lower than it has ever been since 1899, while the number of deaths from small-pox was 85, against 161 in the previous year, and 577, the average of the preceding 5 years. The mortality, however, from dysentery and diarrhœa was higher in 1898 than the average of the previous 9 years. The birth-rate fell considerably below that of the previous year owing to a considerable portion of the female population having left Calcutta during the plague scare. During the year under review 192 deaths were attributed to plague—181 in the town and 11 in the suburbs.

The Health Officer calls attention to the high mortality among infants in Calcutta. In the Mahomedan community the rate of infant mortality was 634·5 out of every thousand births. That rate is nearly three times the rate among the Christian population. The registration of deaths is so unreliable that no explanation of this great difference can be obtained from that source. "The infantile mortality of Calcutta must remain high," writes the Health Officer, "until the town is opened out and a higher standard of personal hygiene, including midwifery practice, is attained."

Owing to the opposition shown to preventive inoculation against plague it was deemed advisable to suspend vaccination work for nearly three months, as the people mistook the vaccinators for plague inoculation officers, and went the length of mobbing and assaulting them. The number of cases of vaccination therefore during the year was only 13,255, against 21,620 in 1897. The fact that the majority of those who left town during the plague scare were women and children partly accounts for the decrease in the number of vaccination cases. The Health Officer again calls attention to the necessity of reducing the statutory period for compulsory vaccination.

Samples of filtered water supplied to the city were analysed, as well as samples of water drawn from the settling tanks at Pultah. The results were satisfactory, the filter-beds were found to be working well, and the drinking water to retain its general purity. Samples of water from foul tanks and wells, as well as of milk, *ghee*, and other articles of food, were also analysed. The illuminating gas supplied to the city was periodically examined.

The price of rice and *dhal* was below the average of the preceding 5 years. Common rice, the staple food of the poor, sold at 5*s.* 10*d.* per maund, against 6*s.* 10*d.* in 1897–98.

Conservancy.—30,508 waggon loads of refuse, etc., were removed from the town and a part of the suburbs, and sent to the square-mile. This figure exceeds those of any of the previous 5 years except 1897–98. 81,802 cart-loads of refuse, etc., from the rest of the suburbs were likewise collected and disposed of. A scheme for the supervision of conservancy work by dividing the wards into blocks and an afternoon service was sanctioned by the Commissioners and put into operation. The cost of the new arrangements was less than the combined cost of the old conservancy establishment and the extra gangs employed in the previous year. Owing to the unsatisfactory character of the service-privy system it has been proposed to gradually abolish it by having house privies for respectable people connected with the sewers, and getting the owners of bustees to construct proper public latrines for the use of their tenants. The Health Officer forcibly points out the highly insanitary condition of the cow-houses in the city and the enormous profits made by cow-keepers by watering milk. The following statement shows the number of tanks filled up and improved during the year :—

Tanks filled up.	Tanks improved.	Other tanks under operation.	Total.	No. of prosecutions for not filling up tanks.	Fines.

LIBRARY OF THE BOMBAY BRANCH OF THE ROYAL ASIATIC SOCIETY.

ABSTRACT OF THE REPORT OF THE HEALTH OFFICER OF CALCUTTA FOR 1898.

(*Dr. J. Nield Cook.*)

Except for the advent of plague the year was an exceptionally healthy one, and in spite of the occurrence of a comparatively mild outbreak of plague, which accounted for 192 deaths, the death-rate for the year was appreciably below the average. This was partly due to the comparatively low mortality from cholera and small-pox, but the statistical results of the year were complicated by a considerable exodus that occurred in consequence of the plague scare, and the absence of reliable data to show how many went and how long they stopped away. The outbreak of plague, from the appearance of the first case discovered in April to the time I handed over charge on the 22nd of July, is dealt with in a separate report. Since that date I have had nothing to do with the plague except as a member of the medical board, which issues the weekly statistics of the health of the town and port, and am consequently unable to report on it.

Meteorological Conditions.—The variations from the normal in barometric pressure were inconsiderable, and do not appear to have exercised any appreciable influence on the health of the town. The temperature during the first quarter was slightly below the average, 0·6°, during the second very slightest below normal, the difference being only 0·1°, during the third 0·8° below, and during the fourth 2·3° below. So, on the whole, it may be said to have been a fairly cool year. The humidity was practically normal in January and February, but 7 below in March. In the second quarter it was 1 above normal, in the third 3·6 above, and in the fourth 4·6 above. 69·88 inches of rain fell during the year, against an average of 66·39, the bulk of it falling between the last week of June and the third week in July. There was a coincident decline in bubonic plague, from over 20 to under 5 cases in the week.

Price of Food.—The price of mutton was above the average, that of beef and ghee about the same, and that of rice and dhal below it. Common rice, which is the best index of the food of the poor, sold at 5*s.* 10*d.* a maund, against 6*s.* 10*d.* in the preceding year.

Vital Statistics: Births.—The total number of births registered was only 9,530, giving a birth-rate of 13·9 per 1,000, against 12,584 and 18·4 in the preceding year. The rates are calculated on the census population of 1891. The low birth-rates in Calcutta generally are due to the population being to a considerable extent a floating one and the number of women being comparatively small. Amongst the Hindus there are 174 males to 100 females, and amongst the Mahomedans, 197 to 100. The exceptionally low birth-rate in 1898 was due to the plague exodus, which affected the female population more than the male. The male to female births were in the proportion of 114 to 100.

The Christian population was the most prolific, with a birth-rate of 18·8, the Hindus coming next with 12·44, and the Mahomedans last with 11·2.

General Mortality.—The total number of deaths was 23,343, against 24,665 in the preceding year. The death-rate, 29·8, was the lowest since 1893. The comparatively low death-rate was partly due to the year being a healthy one, no considerable outbreak of epidemic disease occurring, the mortality from cholera, small-pox, and fevers being well below the average, and partly to a reduction in the population during a portion of the year, due to the plague scare. According to locality, the death-rate varied from 12·7 in Park Street, which is hardly a fair example, as it is largely inhabited by Europeans, who send their children home and retire themselves if their health breaks down, and 36·8 in Sukea's Street. The mortality in the canal area (34·5) and suburbs (35·5) was higher than in the town, though lower than in the preceding year.

Mortality according to Age.—The mortality was lower than in the preceding year under all the age periods, most noticeably between the ages of 20 and 40. The infantile mortality appears to have been higher in the town than in the suburbs, which is in all probability due to closer aggregation, whilst the mortality amongst adults was higher in the suburbs

where the water-logged state of the ground predisposes to fevers and bowel complaints. The low mortality under 5 years was no doubt partly due to the number of children and pregnant women who left the town.

Comparative statement of death-rates according to age groups.

Year.	Under 1 year.	1—4 years.	5—9 years.	10—19 years.	20—39 years.	40—59 years.	60 years and upwards.	Total.
1897	458·5	58·3	21·8	17·7	26·2	26·6	69·3	36·1
1898	368·5	46·6	16·9	14·9	18·6	23·1	68·0	29·8

It has already been shown that the infantile mortality was below the average owing to the exodus. Still the bill was a very heavy one, and amongst the Mahomedans living in the town reached the enormous number of 634·5 to every 1,000 births, whilst among the Christians it was only 217·7. The Christians in the town are as a class poor and not specially noted for cleanliness, and they live under the same conditions of soil and climate as the Mahomedans, so it is difficult to understand why the mortality amongst the one class should be nearly three times that in the other. The causes of death registered are so unreliable as to give no clue to the explanation. The infantile mortality of Calcutta must remain high until the town is opened out and a higher standard of personal hygiene, including midwifery practice, is attained. It is further conduced to by the women in many cases working on a poor diet up to the time of confinement.

Though the actual number of deaths was much greater among males the ratio per 1,000 of the population was very much higher among females, being 37·5 in the latter to 25·7 in the former. The female mortality rate is higher at all ages, but most noticeably between the ages of 10 and 20, the age of marriage in the East, being 19·9 amongst females and 12·1 amongst males.

If "other classes" (58·0), of which the numbers are small, be excluded, it appears that the Mahomedans had the highest mortality (30·3), the Hindus intermediate (28·8), and the Christians the lowest (27·1).

The following table shows that the mortality was below the average of the previous 5 years in every ward of the town and suburbs except Ward 12, Fenwick Bazar, where it was 0·2 above. In the added area the difference was considerable. Cholera was over 2 per 1,000 in only one ward, added area, Ward 1, Shampukur. Plague was worst in Ward 12, Fenwick Bazar, smallpox in the added area, Shampukur. Fevers were worst in Ward 5, Jorabagan, in the town, and accounted for a heavy mortality throughout the added area and suburbs, especially the former. Bowel complaints were worst in Wards 1 to 3 in the town, and were especially prevalent throughout the whole of the added area and suburbs, except Alipur. It will thus be seen that though the mortality from all causes was lower than usual in the added area, that locality is still noticeable for its high mortality from preventable disease.

Special causes of mortality: Fevers.—The mortality under this head in the town and suburbs combined, 6,060, was lower than it has been since the year 1889, which is satisfactory, as the mortality from this cause had been exceptionally high for some years, and it was feared that the increase was due to general deterioration of the town site rather than a cyclical wave of increased intensity. The added area and suburbs, which are ill drained and contain a large amount of stagnant water, were naturally the worst. The sewerage of the latter is being carried out, which may be expected to bring down the fever rate. The returns of deaths from fevers in 1898 were lower than they should have been, as after the appearance of plague many people registered deaths under "other causes" which would in other years have been registered under fevers. Surgeon-Major Ross and Dr. Daniel were working in Calcutta during the year on the mosquito hypothesis of the causation of malarial fever, and there appears to be now sufficient ground for basing practical measures on this hypothesis. I hope shortly to submit proposals for the employment of a few men in the extermination of mosquitoes in their breeding grounds. The cost will be small, and if it does nothing else it will add to the comfort of the people by removing a cause of irritation which is often the subject of complaint. If, as there is good ground for believing, it reduces the mortality from malarial fevers, which are the principal cause of the heavy mortality, especially in the suburbs, the health of the town will be manifestly improved at a much smaller cost than is entailed by any of the usual sanitary measures.

Cholera.—The mortality from cholera was below that of every year since the amalgamation of the suburbs with the town of Calcutta. The number of deaths was 665, against 2,181, the average of the nine years from 1889 to 1897, giving a death-rate of 0·9, against 3·2 per 1,000 of the population. Of these 665 deaths, 457 took place in urban Calcutta, falling short of the average of the preceding ten years by 895, and 208 occurred in the suburbs, falling short of the average of the previous nine years by 663. The figures for the two areas for the past eleven years are as follows :—

—	1888.	1889.	1890.	1891.	1892.	1893.	1894.	1895.	1896.	1897.	1898.
Town	1,734	1,079	963	1,553	1,257	596	1,118	1,302	2,377	1,543	457
Suburbs	—	1,236	916	1,402	762	273	577	797	1,072	806	208
Total	—	2,315	1,879	2,955	2,019	869	1,695	2,099	3,449	2,349	665

The mortality according to season is shown by the following monthly figures, namely:—

January.	February.	March.	April.	May.	June.
31	89	117	147	75	55
July.	**August.**	**September.**	**October.**	**November.**	**December.**
18	13	12	11	5	92

From these figures it will be perceived that the highest mortality was, as usual, in March and April. The mortality in December, however, was higher than is ordinarily the case. This was owing chiefly to a number of pilgrims for Saugor and Triveni succumbing to the desease in and about Kalighat on the way to and from their places of pilgrimage, and to their contaminating Tolly's Nullah near the ghâts, and thus communicating the disease to many residents visiting Kalighat to bathe, make offerings to *Kali*, and feast near Tolly's Nullah. Besides these imported cases, at least 30 fatal cases occurred in December amongst such visitors from other parts of the town.

Of the 665 cases, 101, or 15·1 per cent., were imported from places beyond the limits of Calcutta. The mortality was highest in Jorabagan, Burtolla, Shampooker, Bhowanipur, and Jorasanko wards, with 53, 52, 50, 44 and 43 deaths, respectively.

The cases were mainly isolated ones. In only a few places did the disease show any distinct tendency to localisation within small areas, and the cases which took place in such areas were generally few. Thus, in the Sabjibagan busti, Chetla Road, in Ward 23, there were four cases. The first was a girl of 12 years of the Bagdi caste, who was attacked on the 4th and died on the 6th February. No special cause was traced in her case. She contaminated a tank in the busti, and three other cases followed. They were all females of the Bagdi caste. One was a woman of 20, who was attacked on the 5th February and died the same day. The second was a girl of 8, who was attacked on the 7th February and died the same day. The last was a woman of 28, who was attacked on the 7th and died on the 9th February. A small outbreak occurred in the two adjacent bustis, 236 and 242, Upper Circular Road. The cases were all of conservancy coolies of Wards 2 and 5, and the original cause of the outbreak was probably the same in both bustis. The first case took place in busti No. 236, where one of the coolies of Ward 2 was attacked on the 14th April and died the same day. The attack was associated with the consumption of rotton sweetmeats obtained by begging from shopkeepers on the Bengali new year's day. The second case, also a coolie of Ward 2, was attacked on the 15th and died on the 16th April. The third and fourth were also coolies of Ward 2; one was attacked on the 16th April and died the same day, the other was attacked on the 16th and died on the 17th April. In busti No. 242 there were two attacks on the same day that the last case in busti No. 236 died. The first was a coolie of Ward 2, who was attacked on the 17th April and died the same day; the second, a coolie of Ward 5, was attacked on the 17th and died on the 23rd April. In busti 64, Machuabazar Street, there were four attacks on the same day and all of either the Chamar or the Dosad caste. From the history it would seem that they had been feasting together, but no distinct cause of attack could be made out. The men were attacked on the 10th May, and three of them died on the 11th, and the fourth on the 12th May. At 66, Kansaripara Road, in Ward 22, there were three cases, all Mahomedan boys between 5 and 10 years of age. The first was a boy of 5, who was attacked on the 10th December and died on the 14th. The cause of attack would seem to have been polluted drinking water supplied by a Bhisti in his skin bag, with which he had been carrying tank water for watering roads. This patient contaminated a foul tank which directly communicated with another, and thus two more cases took place close to those tanks. One was a boy of 10 years, attacked on the 11th December, who died the same day; the other was a boy of 9, who was also attacked on the 11th and died on the 15th December.

Small-pox.—As regards the prevalence of small-pox, the year 1898 is to be regarded as a non-epidemic one, the number of deaths recorded from this cause being 85, against 161 in the previous year, and against 577, the average of the preceding five years. The disease occurred in all the wards excepting Waterloo Street, Hastings, Baniapookur, Ballygunge, Bhowanipur, Alipur, and Khidderpur. Except for two cases in Entally in March and five in Watgunge in December, the disease may be said to have been confined to the old town and canal area. Small-pox was present in Calcutta during all the months of the year except October. The town would have been likewise free from the disease during September and November were it not that two cases which had occurred in Shampookur in August ended fatally in September, and a fatal case occurred in the same locality in November, and that two cases were imported from Hong Kong in September, and being admitted in the small-pox hospital recovered.

As in ordinary years, the prevalence of the disease was in the form of an outbreak, which, commencing from the close of the previous year, attained its height in March and April and practically ended in August, and which was followed after an interval of about three months by the commencement, in the month of December, of a fresh outbreak, which attained its full force in the following year. 142 cases of small-pox came to notice in the course of the year 1898, of which 85, or 59·4 per cent., proved fatal. Of the 142 cases, 33, or 26·7 per cent., were vaccinated, 4, or 2·8 per cent., were inoculated, and 88, or 61·9 per cent., were unprotected, while in 12, or 8·4 per cent., the condition as regards previous protection could not be ascertained. The mortality among the vaccinated cases was 44·9 per cent., among the inoculated 100·0 per cent., and among the unprotected 63·6 per cent.

Dysentery and Diarrhœa.—The mortality from dysentery and diarrhœa was higher in 1898 than the average of the previous nine years. The number of deaths was 3,074, against 2,896, the mean of the nine years from 1889 to 1897, giving a death-rate of 4·5, against 4·2 per thousand of the population. Of the 3,074 deaths, 1,586 occurred in the

town, exceeding the average of the previous decennium by 190, and 1,488 took place in suburbs, exceeding the average of the previous nine years by 26.

Other Causes.—It has been shown that the mortality under the special heads of cholera, small-pox, and fevers was much below the average. The mortality registered under "other causes" was, however, above the average, being 10,268, against an average of 8,560, giving a difference of 1,708. Of some of the principal causes of this increase, the deaths registered under phthisis were 431 more, those under asthma 617 more, and those under bronchitis 191 more than last year.

Vaccination.—Vaccination against small-pox was carried on by the Municipal Vaccination Department during the greater part of the year 1898. Soon after the declaration of plague in Calcutta, and the introduction of preventive inoculation against plague, some of the vaccinators were mobbed and assaulted, and the Chairman on the 3rd May stopped all vaccination work for the time being, so that from the 4th May to the 21st July there was practically no vaccination done, the work being confined to the houses of a few respectable Native gentlemen where small-pox occurred. From the 22nd July, although the work was resumed, there were no applications for vaccination at the stations, and the vaccinators were afraid to go to the bustees for fear of being molested. The Deputy Superintendent of Vaccination was therefore obliged to accompany them to the bustees and explain to the people that they had nothing to do with the plague inoculations, and being well known to them, persuaded some to have their children vaccinated in their own houses, these first persons persuading others to bring their children to the stations. In this way the normal state of things was gradually attained.

The total number of persons vaccinated during the year was 13,255, against 21,620 in the previous one. Of these, 11,569 were primary and 1,686 were re-vaccinations, against 13,297 and 8,323 respectively in 1897, thus showing a decrease of 1,728 primary and 6,637 re-vaccinations. The decrease of primary operations was mainly due to the removal of a large proportion of the residents from the town during the plague scare, and also to the comparative immunity from small-pox during the year. The very small number of re-vaccinations done in 1898 is to be ascribed to the latter cause alone. Besides the above numbers, which show the work done by the Vaccination Department of the Corporation, 158 primary and 2,190 re-vaccinations were performed by Government officers of the Animal Vaccination Department, Calcutta, in private European houses, and in public institutions, such as hospitals, jails, asylums, &c. Were these figures combined with those shown in the returns of this department, the total number of primary and re-vaccinations done in Calcutta during the year 1898 would amount to 11,727 and 3,876 respectively.

Of the 11,569 primary operations, 10,931, or 94·48 per cent., were successful, 91, or ·17 per cent., were unsuccessful, while in 547, or 4·7 per cent., the result could not be ascertained. The rate of success, calculated on the ascertained cases, was 99·07, against 97·59 in the previous year. Of the 1,686 re-vaccinations, 244, or 14·47 per cent., were successful, 656, or 38·91 per cent., were unsuccessful, while in 786, or 46·6 per cent., the result was not ascertained. If the unknown cases are excluded from the total, the rate of success in the re-vaccinations was 23·68 per cent., against 16·51 in the previous year.

Of the total of 13,255 persons vaccinated, 7,117 were males and 6,138 were females. According to nationality, 9,247 were Hindus, 3,473 Mahomedans, 425 Christians, and 110 of other classes. Considered according to age, 3,198 were under 1 year, 8,025 1 year and under 6 years, and 2,032 were 6 years and over. Of the 11,569 primary operations performed in 1898, 7,907 were Hindus, 3,253 Mahomedans, 304 Christians, and 105 other classes; while 3,198 were under 1 year, 8,025 1 year and under 6 years, and 346 were 6 years and over.

Primary vaccination is carried on in Calcutta under the Compulsory Vaccination Act, which provides that the parent or guardian of a child is to get it vaccinated within one year from birth, and that if on the expiration of that year the child is found unvaccinated the parent or guardian may be prosecuted, and an order obtained from a magistrate for the compulsory vaccination of the child. The procedure which is accordingly adopted is for the Registrar of Births at the time of registration to issue a notice to the parent or guardian of the child to get it vaccinated within 12 months from the date of birth, and to send a corresponding notice of the birth to the Vaccination Department, and for the Vaccination Department as soon as possible after the child has been vaccinated to grant a certificate showing the result of the operation, and to send a corresponding certificate to the Registrar of Births for record. When twelve months have elapsed from birth, if the child is found unvaccinated, though in a fit state to be vaccinated, prosecution is instituted

against the parent or guardian under the powers conferred by the Amended Vaccination Act. Moreover, house-to-house enquiry is made for unprotected persons by the male and female vaccinators of the department, and for every person over one year of age who is found unprotected, and who, or whose parent or guardian, refuses to have vaccination done, a notice is issued to have the vaccination performed within 15 days from the receipt of notice, and, in default, the party responsible is prosecuted. The unwillingness of the majority of the residents of the town to have their children vaccinated until they are at least a year old, and the fact that the law allows them to do so, have been brought to notice in previous reports, but unless the statutory period for compulsory vaccination is reduced the protection of the infant population cannot be secured. In the year under report there were 17 cases of small-pox reported under one year of age, of which 13 ended fatally.

Vaccination was performed during the year 1898 with lymph obtained either direct from vaccinated calves, of which the department received a supply of 446 in the course of the year from the Government Animal Vaccination Depôt in Calcutta, or with lanoline vaccine paste received from the same source. The paste was found very convenient for vaccinating poor people at their own houses who were unable to pay any charge for vaccination. It was also used in the stations during the greater part of the hot and rainy seasons, when the attendance was very limited, and where it was found very expensive to have the operation done from calf to arm. In a very limited number of cases humanised lymph was also used in the houses of orthodox Hindu families, or amongst people who had objections to the use of the calf lymph.

The following table shows the comparative rates of success in primary vaccination obtained from the use of calf lymph, lanoline paste and humanised lymph, respectively :—

—	Calf lymph.	Lanoline paste.	Humanised lymph.
Total No. vaccinated	3,736	6,384	24
No. in which result was ascertained	3,488	6,211	24
No. successful	3,463	6,166	24
Rate of success per cent. on ascertained cases	99·2	99·2	100.0

At present lymph calves are conveyed in common hackney-carriages from the Animal Vaccination Depôt to the Vaccination Stations and other places where people have to be vaccinated. But this system is objectionable for two reasons. First, the use of public hackney-carriages for carrying vaccinated calves is very undesirable, as they cannot be easily or completely disinfected in a short time, if at all, and we cannot expect the man who supplies them not to use them for any other purpose. Secondly, for the supply of such carriages we have to depend upon a contractor; and if he fails us we find it difficult to get carriages. To obviate this difficulty a proposal was submitted to the Commissioners in March for the construction and equipment of four specially constructed carts for the conveyance of calves, which has not received sanction.

ABSTRACT OF THE REPORT OF THE MADRAS MUNICIPALITY FOR 1898-99.

(*R. E. Ellis, Esq., Acting President.*)

Births and Deaths.—The total number of live-births registered during the year 1898 was 18,694, against 18,702 in 1897, showing a decrease of 8. The ratio per 1,000 per annum calculated on the census population of 1891 was 41·3, the same as the previous year. The decrease is without doubt due to the hard times, the price of the staple grains remaining very high till towards the close of the year. The number of still-births registered during the year was 384, a proportion of 2·0 still-births to every 100 born alive. No doubt there is still considerable concealment owing to popular prejudices, and dead children are easily got rid of in this country. The male births numbered 9,721 and the female 8,973, giving a proportion of 108·3 males to 100 females.

According to caste the birth-rate among the Mahomedans was 42·9 per 1,000 ; among the Hindus, 41·5, and among the Christians, 37·7.

Mortality.—During the year 1898 there were 20,286 deaths registered in Madras, giving a death-rate of 44·8 per 1,000, calculated on the census population of 1891, against 16,086, or a ratio of 35·5, in the previous year, the average for the decade being 17,976·9. In 1897 the number of births was greater than the deaths by 2,616, and in 1898 the number of deaths was greater than the births by 1,592. Of the 20,286 deaths registered, 9,953 occurred among males and 10,333 among females, giving a proportion of 96·3 to 100.

The number of deaths according to nationality was: Europeans 99, Eurasians 472, native Christians 892, Hindus 16,449, Mahomedans 2,368, and others 6. The ratios per 1,000 are 36·8 among Christians, 45·8 among Hindus, 44·5 among Mahomedans, and 10·0 among "others," against 29·7, 35·7, 38·7, and 13·4 of the previous year.

During the year under report the number of deaths from fevers was 5,489, against 5,484. The deaths from fevers were practically the same as in 1897. In October the numbers registered suddenly showed a great decrease, which was attributed to the public fearing investigation on account of plague if they said that a relative died of fever, so they assigned the death to some other cause. The total mortality was higher than it had been for some years. No definite cause can be assigned for this, after the exclusion of a large number of cholera cases. A close investigation was made by the order of Government to ascertain whether concealed plague had anything to do with it, but it was satisfactorily determined to be due to the operation of general causes combined with a small epidemic of cholera. The deaths from "Measles" and "Diarrhœa and Dysentery" have risen high, *i.e.*, from 410 to 775 and from 2,000 to 3,302 respectively. But the mortality from small-pox remained almost the same, viz., 116 against 114, while cholera rose from 169 to 778, the highest recorded since 1891. Seven deaths occurred from plague.

Small-pox.—The total number of deaths registered in 1898 from small-pox was 116, against 114 of the previous year. The small-pox of 1898 was a continuation of that which commenced in the beginning of 1897. The incidence on the vaccinated and unvaccinated is shown in the following table :—

——	Attacks.	Deaths.	Fatality.
Unvaccinated	175	50	28·6
Said to be vaccinated but no marks	104	40	38·4
Vaccinated	177	26	14·7
Had previous attack of small-pox	4	—	—
Total	460	116	25·2

——	Total deaths.	Under 10 years.	10–20.	Over 20.
Unvaccinated	55	43	6	6
Vaccinated	23	14	4	5

Cholera.—The outbreak was by no means of a sudden nature. Cholera was prevalent in the city in a sporadic form throughout the year 1897. On looking over the weekly proceedings of the Board of Health it is found that, after a comparative freedom of several months from cholera, two fatal cases were reported in the week ending with 11th June, 1897, of which one was said to be imported. Thereafter every week furnished some deaths from cholera under the sporadic column, and in September, 1897, during the week ending with the 3rd, the disease even assumed epidemic proportions. Two parcherries, one in the 1st and the other in the 8th division, were the chief centres then affected. This sudden rise in the number of deaths from cholera lasted but a week, yet during the months of October, November, and December cholera continued in a sporadic form. With the advent of the new year, 1898, a change for the worse came on, the number of deaths gradually swelled up, so that in January and February alone there were reported 99 attacks, 67 deaths. This again came down, and during the months of March, April, May, and June there were but 19 deaths reported. This temporary cessation was followed by the outbreak in July, 1898, which continued throughout August, when it was at its height, and September. The highest number of deaths reported in the present outbreak in any one week was 91 for the week ending with 19th August, 1898. When the north-east monsoon set in with full force cholera gradually abated, so that in November and December only 46 and 19 deaths respectively were reported, but it was not until February, 1899, that the city became entirely free. The total number of deaths from cholera in 1898 is 778, and the highest number recorded in any one year since the severe epidemic of 1891, giving a ratio of 1·7 per 1,000.

Plague.—During the year seven deaths occurred from plague, against two in the previous year. All of them were imported ones.

Measles.—The number of deaths registered from measles was 775, against 410 in the previous year, the highest recorded since 1893.

Bowel Complaints.—Under the heads of dysentery and diarrhœa there were 2,750 and 552 deaths registered in 1898, against 1,496 and 504 of 1897.

Infantile Mortality.—There was a visible rise in the rate of infantile mortality during the year under report, from 369·9 deaths to every 1,000 births of 1897 to 404·2 deaths to every 1,000 births in 1898. This can only be accounted for by the general ignorance of the masses in matters relating to management of birth and infancy, coupled with the existence of insanitary conditions and overcrowding in many parts of the town. The total number of deaths for the year registered under this head was 5,525, against 5,052 of last year.

The Price of Food.—The price of food during the year became dearer than in 1897, and continued to remain so till toward the close of the year, causing great distress to the poor classes and exercising a potent influence on their mortality.

Meteorological Conditions.—The Government Astronomer reports as follows :—" Temperature—was below average in January, March, September, and October ; it was normal in November, and above average during the other months. The highest shade temperature recorded was 109·8° on May 9th, the lowest was 59·8° on February 3rd. Rainfall was below average in January and from March to July, and above average in the other months. The excess for the whole year was 19·12 inches. The rainfall during the period 15th October to 31st December was 43 inches, against an average of 26, and a fall last year of only 9½ inches. The greatest fall on one day was 5·65 inches on December 26th."

Vaccination.—During the year 1898–99 the total number of cases vaccinated was 28,186, showing a decrease of 4,896 cases when compared with the year 1897–98. The decrease is accounted for to the less prevalence of small-pox during the year under review, and to the non-vaccination of emigrant coolies, the Natal Emigration Depôt at Cassimode having been closed from November, 1898, on account of plague. When contrasted with the year 1896–97, the work performed during 1898–99 shows an increase of 1,165 cases. Out of 28,186 cases vaccinated there were 16,372 males and 11,814 females. Of the total vaccinated, 25,066 were successful, 1,099 unsuccessful, and 2,021 unknown. The large number of unknown cases was due to the convicts of the Penitentiary undergoing short terms of imprisonment of from 3 to 5 days having been released before inspection of the result. Also to the emigration coolies of the Natal Depôt who, after

vaccination, were rejected as being physically unfit before the results of vaccination could be ascertained.

During the year 1898–99 the revised bye-laws, dated 22nd February, 1898, were put into operation from the beginning of the official year. Under bye-law 5 the parents were bound to produce the vaccinated children for the inspection of the vaccinator. Out of a total of 28,186 cases vaccinated in the depôts, 9,740 cases were brought to depôts for inspection, as required in the memorandum, and in 15,922 cases the parents were reminded and warned to take their children to depôts in order to minimize the prosecutions for failing to comply with the bye-laws. Those cases vaccinated in the Penitentiary and Natal Emigration Depôt, viz., 2,724, were verified by the Deputy Inspector.

The percentage of success, both in primary and re-vaccination, excluding the unknown cases from the total, was 95·79, showing a decrease of ·97 per cent. below the year 1897–98, and it was due to the low percentage of success obtained in re-vaccination.

The following table shows the result obtained in both primary and re-vaccination as compared with the year 1897-98 :—

Year.	Primary Vaccination.				Re-vaccination.			
	Successful.	Percentage.	Unsuccessful.	Unknown.	Successful.	Percentage.	Unsuccessful.	Unknown.
1897-98	24,335	99·56	106	387	6,091	86·97	912	1,251
1898-99	20,147	99·48	105	375	4,919	83·18	994	1,646

Out of 28,186 cases vaccinated, 1,351 were Europeans, East Indians, and native Christians, 2,587 Mahomedans, 24,237 Hindus, and 11 other castes. Of the total vaccinated, 20,627 were primary vaccination, against 24,828 in 1897–98, showing a decrease of 4,201 cases. The percentage of success in primary vaccination was 99·48, showing a small decrease of ·8 per cent. against 99·56 in 1897–98. Among adults 7,559 re-vaccinations were performed, with a percentage of 83·18 of success, against 86·97 in 1897–98, showing a decrease of 3·79 per cent. In G.O., No. 484 M. Mis., dated 13th April, 1899, par. 4, it has been pointed out by the Sanitary Commissioner that the rate of success arrived at after inspection of 1,000 cases of re-vaccination was between 75 and 60 per cent., which is considered a fair percentage. The attention of the vaccination staff has since been drawn to the remarks of the Sanitary Commissioner.

During the year 13,643 infants were vaccinated, against 15,323 in 1897–98, showing a decrease of 1,680 cases, with a percentage of 99·58 of success, against 99·70 in the previous year. Out of 28,186 cases vaccinated, 13,643 were infants under one year, 6,669 above one and under six years, and 7,874 above six years of age.

Plague Measures.—When the plague broke out in Bangalore, at the instance of Government a scheme of defence for the City of Madras was drawn up with the aid of the Sanitary Commissioner, and immediate steps were taken to carry many of its suggestions into effect. The number of municipal hospitals was increased from two to four, and everything made ready in all of them for immediate occupation.

Government having sanctioned the formation of caste hospitals by the leaders of various communities to provide for those persons, who, from religious or other motives do not care to become inmates of the municipal hospitals, meetings were organised and held by the Commissioners with the object of explaining the situation to the population, and collecting funds to defray the cost of erecting or leasing suitable buildings for the purpose. Government agreed to pay half the cost of establishment and maintenance in each case, after formal approval of the site and general arrangements.

The outcome of the movement was—

(1.) A caste hospital, fairly completely equipped, for Brahmins in Edward Elliot's Road, 8th Division.

(2.) A Gosha hospital, with segregation building adjoining, in Peter's Road, 7th Division, also complete.

(3.) A camp hospital for Brahmins on the beach, 7th Division, as yet uncompleted.

(4.) A Persian hospital in Tondiarpet, 1st Division.

(5.) A promise from Rajah Sir Savalay Ramasawmy Mudaliar, to bear half the cost of a general hospital in each division—one was begun in 4th Division.

(6.) Sites were chosen or looked for in several other divisions by other communities.

Owing to the cessation of the Bangalore outbreak further action seemed unnecessary at the time, as the danger of an epidemic here became considerably less, but enough had been done to show the readiness of the people to help to provide for themselves in a time of need.

Segregation Camps.—No new camps were put up, partly because the existing accommodation was sufficient to meet the first rush, and partly owing to the resolution of Government exempting from segregation all persons who had been inoculated, which, it was anticipated, would be freely resorted to.

The small camp opposite Perambur station is used for the detention of travellers from infected areas who fail to give satisfactory addresses on arrival. The number of persons thus detained during the year was 498. All cases arriving by train with fever or other suspicious symptoms are sent to the Perambur hospital for observation.

Several sites have been selected for the erection of health camps in case it became necessary to evacuate any seriously infected district, but only one has been put up as yet —on Pudupet plain, though materials are kept ready for immediate use in three other places.

Four military officers were put on special plague duty by the Government in the month of September, their instructions being to supervise and be responsible for the proper working of all plague measures in their respective districts, including the disinfection of houses and tracing of contacts. Each officer had a gang of 25 sepoys who had been trained in disinfecting by the Sanitary Commissioner. One batch was camped in the compound of the Wallajah Road Police Station, where the plague officer also had his office, another in the compound of the Vepery segregation camp, and the rest on the Washermanpet maidan. These men were supplied with all the necessary apparatus for disinfection, and, on a case being reported, they proceeded to the house and assisted in the removal of the contacts to the camp, afterwards disinfecting the premises.

Each plague officer had also a clerk, peons, &c., and a bicycle, that urgent messages might not be delayed. As there was practically no work in the beginning they undertook the supervision of the parcherry cleaning gangs, which were specially instituted for the purpose of cleaning up as far as possible all the dirtiest spots in the city before the advent of plague. After the cleaning, the houses of those persons who could not afford to do it themselves were whitewashed gratis, and notices were served on large numbers of those who could afford it. Leaflets were distributed all over the town calling upon the residents to clean and whitewash their premises, to which many responded.

Work done—	1st Division	... 7,134 rooms	whitewashed.
	2nd and 3rd Divisions ...	... 2,334 huts	,,
	4th, 5th, and 6th Divisions ...	... 592 houses	,,
	7th and 8th Divisions ...	... 1,174 houses	,,

In March, as the danger of an outbreak was not so imminent, 75 of the sepoys were sent back to their regiment, and 25 only were retained for emergencies.

During the first half of the year the system of surveillance which had previously been in force was continued. All passengers from infected areas had their names and addresses taken at Perambur station, and the slips were distributed among the Sanitary Overseers, who visited them daily in their homes for ten days. Persons who did not know where they were going were either detained for 10 days at the Perambur camp or were accompanied by coolies till they had fixed on a residence. The system worked fairly well, only a small proportion of the travellers escaping observation, but it gave the Overseers in the more thickly populated wards a great deal of additional work, and was necessarily somewhat detrimental to their ordinary duties.

When the plague broke out in Mysore, the number of persons coming to Madras from infected districts was enormously increased in consequence of the proximity; and the passport system was introduced all over the Presidency.

All persons arriving by train from places notified to be infected were required to procure a passport at Perambur, which bound them to present themselves before an Inspector daily for 10 days. If they failed they were liable to prosecution. To meet the increase of clerical work at Perambur several writers were appointed, and to observe the passport

holders in the city seven Plague Inspectors having the qualification of Sanitary Inspector or Hospital Assistant were established either in the offices of the divisional registrars or in police stations. It was the duty of these inspectors to sign up daily all passport holders who presented themselves during their office hours ; to keep a register of the same ; to intimate to District Collectors the departure of any of their clientèle before the expiry of the observation period ; to hunt up all absentees and defaulters at their addresses, and to visit daily at their homes persons who have been exempted by reason of illness or otherwise from attending the plague office. Defaulters were prosecuted by the Divisional Sanitary Inspectors. The system worked fairly well, but, of course, a certain percentage of arrivals altogether escaped observation, and could not be traced either by the sanitary staff or the police. It is good luck alone that has saved the city from indigenous cases, which might very well have followed, if one of those persons who eluded the utmost vigilance manifested had developed plague and died unknown.

It will be noticed that after the Bangalore outbreak the number of possibly infected travellers arriving rose, and again when Vellore and its neighbourhood became infected there was a still further increase. So greatly indeed was the work of the Plague Inspectors in some districts, notably the 2nd, 5th, and 7th, increased that they had to be relieved by assistance from the sanitary staff and the Hospital Assistants under the orders of the plague officers. In addition to the seven Plague Inspectors two nurses were engaged, one for Northern Range and the other for the Southern Range, to see at their homes all gosha women and other females who had an objection to leave their homes. The number of passport-holders who could not be traced was about 4 per cent. of the total number of passports issued.

Further precautions included a daily scrutiny of the mortality all over the town, coupled with minute enquiries into every case in which two or more deaths had occurred in one house at short intervals of time. The sanitary staff also had orders to enquire into the cause of every death that they happened to hear about, and to immediately report any suspicious circumstances. All cases of illness amongst passport-holders were at once reported and investigated by some one competent to give an opinion.

A good deal of inconvenience was caused to persons who were constantly travelling and to railway employés. The former class were to a great extent relieved by the G.O., which allowed all persons possessing a properly authenticated inoculation certificate to go free without being subjected to surveillance, and the latter by the issue of permanent passes, the railway authorities having agreed to immediately report all illness among them.

Passport-holders among the railway employés of the Madras Railway were examined by the Railway Medical Officer, those going to Fort St. George by the Fort Surgeon, and to regiments by the Regimental Medical Officers. Persons under the treatment of qualified medical practitioners had their passports signed by them. Considering the annoyance and inconvenience of attending the Plague Inspector's office daily, especially when it seemed to the individuals concerned that they had not come from an infected spot, the general public must be congratulated on the way they have submitted themselves to regulations which were enforced for the good of the community.

The issue of passports to arrivals from Calcutta was undertaken by the Port Health Officer and the daily examination by the Municipal Plague Inspectors. All coolies working on ships from infected ports were disinfected before being permitted to return home, and any absentees from work were visited at their homes by a Hospital Assistant to make sure that their absence was not due to plague contracted on board the infected vessels.

The question of examining all arrivals by road at the toll-gates was discussed and fully considered, but abandoned as impracticable ; and reliance had to be placed on the arrangements made by the District Collectors for preventing foot-passengers from conveying the disease.

The issue of passports to travellers by the S.I.R. was conducted at Chingleput station, since it was considered that Madras would be thereby more effectually protected than by issuing them at Chetput or Egmore.

Judging that if a large number of the rodent population of the town, which undoubtedly are most prone to the attack of the plague, could be destroyed before the disease became indigenous, a large quantity of pabulum eminently suited to the needs of the plague bacillus would be removed, and fewer chances given it to develop and be distributed, it was determined to offer rewards for each dead rat, bandicoot, and mouse produced. The Commissioner of Police kindly undertook the distribution of the money at the different Police Stations, and after the tail of each animal had been cut off to

prevent its subsequent production as a claim for pies it was put in a bucket. These buckets were twice daily removed to the rubbish depôts, and their contents cremated in small iron incinerators.

Towards March, 1899, it was seen that the numbers killed did not show any tendency to diminish; it is obvious, therefore, that it was more or less hopeless to make any permanent impression on the total rodent population. Added to this there was some suspicion that persons might be induced to breed them for the sake of the reward, and it was known that field rats were constantly being brought in. So the reward was reduced to one anna a dozen to see what the effect would be before ceasing to offer it altogether.

During September inoculation with Haffkine's Prophylactic was begun in the Health Office, the object being to protect first of all the sanitary staff before the rush came, that their work might not be interfered with. A little later two public demonstrations were given in Triplicane to familiarise people with the process, and show that it was not necessarily followed by death or permanent disability of any sort. One or two of the Commissioners took the matter up, and having been operated on themselves to give confidence to the crowd, persuaded many other people to come forward. Several public lectures were given on inoculation by the Sanitary Commissioner and Deputy Sanitary Commissioner, and the times and places where people could be inoculated were freely advertised. At first the Deputy Sanitary Commissioner, Major Bannerman, I.M.S., performed most of the operations, but when the numbers applying for protection became too high, the four English Plague Medical Officers lent by Government to the Municipality relieved him. A Lady Apothecary, Mrs. Huffton, was appointed to inoculate gosha and other females at their homes.

The outlook cannot be considered to be very bright. Plague is indigenous within 80 miles of Madras, and though the number of cases has not been very great, yet there is good reason for fearing that they will become more numerous in course of time. No reliance can be placed in the theory, which seems to find favour in the eyes of many, that plague cannot flourish on the east coast and that if it does establish itself in Madras the result will not be serious; nor can the precautions taken, carefully devised and zealously put into execution though they be, be deemed a full and sufficient safeguard against an invasion, for loop-holes of escape are to be found in every part of the system depended on. Despite passports and police plague may arrive by rail; notwithstanding the vigilance of Moffussil officers it may enter unknown by road, rats and infected merchandise can introduce it without any one being the wiser. Fortune has so far favoured us, and all the imported cases have been brought to light, but one day she may fail, and he is bold who would dare to say how Madras would fare.

Sanitary Defects and Sanitary Progress.—The Mylapur drainage system has been opened during the year and there can be no doubt that it is on the whole a great success. It is now possible to keep the streets clean and free from very offensive smells, and the gain in dryness of the soil will surely be made evident in the course of a year or two by a diminution of sickness and lowered death-rate. It remains now to connect some outlying parts as Robertsonpet and Kosapet with the system.

Steps are being taken to provide for the drainage of other quarters also, which may possibly be begun before the year is out; and not a moment too soon, for sewers to carry off waste water are by far the most urgent need of Madras at the present. It is true economy to spend money freely on works that will in future be indirectly most profitable. To give an idea of the insufficiency of the present system of sewers it is roughly calculated that about 4,200,000 gallons of sewage are daily disposed of on the existing farms and by drains discharging into the sea. Now the amount of pipe water supplied daily is about 8,210,000 gallons without counting the quantity raised from wells which cannot be estimated. The difference, about 4,010,000 gallons, daily soaks into the soil, except such quantity of it as may be evaporated. Can it be wondered that Madras is damp, swarms with mosquitoes, is a hot bed of malaria, and that the subsoil water level is very high? Of course a good deal of this surplus is utilised without offence in watering the grass and trees of private premises. Some flows into the Cooum and some into tanks, but the fact remains that an enormous quantity is not disposed of at all.

The new sewer in Sydenham's Road has tapped the drains that used to fertilise People's Park, and removed a smell that was the cause of frequent complaints, but, in doing so, more sewage is of necessity pumped on to that water-logged area near DeMellow's Road, the effluent reaching the Buckingham Canal and flowing around one of the water mains on its way.

A new drain was opened at Royapuram which discharges into the sea. This gets rid of a good deal of sewage without nuisance, but at first gave a great deal of trouble by the mouth becoming blocked by sand and the valve being broken by the waves.

For the rest, there has been no important change, some of the sewage being disposed of on farms as before, the remainder soaking into the ground.

There is extreme difficulty in getting night-soil put into night-soil carts and not into rubbish carts, especially in Black Town, since the scavengers make money by the latter procedure. A large number of extra conservancy carts were sanctioned during the year, chiefly for night-soil. It is in the 1st, 2nd, 3rd, and 7th Divisions that the removal of night-soil is so defective. Even though there will shortly be enough carts, it is doubtful whether complete success will be achieved for some time to come, owing to lack of scavengers and proper drivers, and the absence of all power over this class of persons. They strike work whenever it seems good to them, and often on account of events which are in no way connected with the municipality, but have originated in private quarrels or differences with the police. Government has been addressed on the subject of a labour law, but no decision has yet been obtained.

Twenty-four Conservancy Overseers were temporarily appointed on a salary of Rs. 15, whose sole duty is to attend to the better working of the carts and coolies, but so far the improvement has not been very noticeable, and it is probable that many of them will before long be dispensed with. The range of the Sanitary Overseers' work should be considerably enlarged by providing them with bicycles to be paid for on the monthly instalment system, and it is hoped they will all avail themselves of the opportunity.

Many streets and lanes are made almost impassable by people committing nuisance, especially in 1st Division. This is not wholly for want of latrine accommodation either public or private, for all open places are fouled whether a latrine is handy or not; and children and servants are habitually sent to defecate outside a house by the owner thereof, even though it has a latrine attached. Housewives are as contumacious as ever in the disposal of their refuse, which leads to the very untidy appearance of so many Black Town streets. Those who do not fling it into the street just outside their houses treat the dust-bin merely as a sort of indication of a spot near which rubbish may lawfully be thrown.

The water supply still requires to be filtered before distribution, to remove suspended vegetable matter. There are several places where the main pipes run above ground, and are at times immersed in very foul water and the drainage from rubbish depôts. In other places the delivery pipes run through cross underground drains at right angles, which not only exposes the water to the possibility of contamination, but also affords an obstacle to the passage of floating leaves and debris, which constantly collect at that point and completely block the lumen of the drain. During the latter part of the year many of the branch pipes were raised and cleaned. The accumulated deposit in some cases had almost obliterated the lumen of the pipe, and was found on examination to consist of earthy matter, oxides of iron, &c., together with various animal and vegetable remains, living leeches, and a few dead fish. Of course the supply reaching the houses was greatly increased in quantity and probably also improved in quality by the process.

A certain number of dirty and useless wells were closed during the year, and steps taken to prevent new ones being dug in populous quarters where pipe water could be easily supplied. The well of the Brahmin choultry in Poonamallee Road, known as the "Egmore well," is still held by many to be the best water obtainable in Madras. The Chemical Examiner styles the water "usable." Bacteriologically nothing about it is known. No doubt the water is good, otherwise it would not have acquired such a reputation, but it is most liable to contamination on account of the numberless dirty chatties and vessels lowered into it by the water carriers of the 120 or so houses and institutions that use it, exclusive of casual visitors. The religious beliefs of the frequenters of the choultry forbid them to drink pipe water, so it cannot be closed.

A crusade was inaugurated against the dhobies to prevent them from washing in foul and stagnant water, and to compel them to provide proper and separate places for storing clean and soiled clothes apart from their living rooms. Some literature on the subject was distributed among them. Great improvements could not be affected, owing primarily to their poverty, and secondly, to passive opposition and ignorance of what is wanted and of the necessity for changing their ways. Some years must pass before the dhobies as a whole can be educated up to the modern standard. Meanwhile there remain but few places in which they can be recommended to wash except wells, and there the labour of drawing water is a serious drawback. If only some public-spirited individual would start and superintend one or more dhoby khanas, established and worked on cleanly and

sanitary lines, he would be a benefactor to all Madras. It is hoped that the municipality will be able to provide for a small experimental one in Chetty's Gardens, Triplicane, where there is an unused slaughter-house fit for the purpose, during the current year.

Many market owners were compelled to repair and improve their markets. In several there is now little that can be desired, but nearly all suffer from lack of supervision on the part of the owners over the stall-keepers, who are allowed to block the gangways and generally to make as much mess as they please. The Kotwal Bazaar has begun to put improvements in hand and bids fair, if the problem of control over the stall-keepers can be successfully overcome, to be a pattern institution. The new Municipal Market in the People's Park is rapidly progressing and will probably be a great success, as many applications for stalls have already been received. A beef stall is badly needed for the Smithfield Market, the present arrangement of a dirty shed on a piece of open land being objectionable from every point of view.

Private cattle-yards still are a source of great public danger. Poverty prevents many necessary alterations being carried out, but it is an open question whether a man, who keeps ten cows in a filthy yard and pleads poverty when called upon to pave and drain it, can be justified in his action. Should he rather sell four cows, pave his yard with the proceeds, and keep the other six in a decent way? Many consumers of milk would revolt if they saw it being drawn from the indescribably filthy udder of a buffalo cow, by the almost equally unclean hands of the milkman, into a vessel which has been placed on the ground, reeking with dung and urine, of a close and overcrowded cow-shed. The milk cannot, under such conditions, fail to be contaminated with every pathogenic organism that happens to be present. Public cattle-yards, where a man can rent a few stalls, are badly wanted.

The question of the erection of one or more "infectious diseases hospitals" was again under consideration, and a committee was appointed by Government to decide what could be done.

Great care has been exercised in seeing that the plans of all buildings submitted are properly arranged with regard to sanitation, and many cases have been discovered in which the builders have entirely disregarded the instructions given. The type of plan for native houses is fundamentally wrong; it is almost impracticable to ventilate them properly. Love of privacy and dark corners outweighs all hygienic principles; but, while the privacy of a family is in the abstract to be encouraged, yet, when it goes to the length of excluding all light and air, it begins to merit condemnation. There is a growing tendency to construct long rows of dark and unventilated dwellings for the poor, having regard only to the number of rooms that can be got into the space available, which must be guarded against. There is rarely any adequate provision for bathing-places in private houses, and some public ones to suit all castes are greatly needed.

The work of cleaning covered drains, which had hitherto been performed by contract, was undertaken departmentally by the Health Department and a temporary staff engaged for the purpose in charge of three Special Superintendents. One gang was attached to 7th and 8th Divisions, one to the 5th, and one to the 1st, 2nd, and 3rd. It has also been found necessary to keep a special staff to clean the Mylapur Sewage system and preserve the house connections in good order. The new arrangement has been found to work well, more has been accomplished in a shorter time, and prompt attention could be given to any urgent work. Moreover, many underground drains, the existence of which was previously unknown, have been discovered.

The flushing of drains, inaugurated on account of plague, was also transferred to the Health Department on April 1st, 1898, and the work supervised by the Sanitary Inspectors. The monthly expenditure was thus reduced from £180 to £94 without any loss of efficiency.

Without trying to be too up-to-date and to introduce innovations and modern improvements before either the time is ripe or the general public are sufficiently advanced in their requirements to render them successful, or even desirable, it may fairly be held that the opportunities for the advancement of knowledge and the means for scientific investigations of the most elementary character are further removed from realisation than should be the case in a city of the size and importance of Madras. For example: (*a*) Haffkine's anti-cholera inoculations have been proved to be of immense value, yet they cannot be practised here for lack of material. Who can say with certainty that there are weapons enough at hand to combat a widely-spread outbreak of cholera, such as might occur any year. To Hankinise all the wells in the affected nieghbourhood might or

might not suffice. Even that is working quite in the dark, for no one has the means of telling by what medium the disease is being spread without careful bacteriological examinations. (*b*) The analysis of articles sold for food, of various waters for potability, the chemical examination of substances, such as silt, sewage, deposits, and incrustations of different kinds, can, it is true, be performed by the Chemical Examiner to Government, if he has time, and if he is kind enough to undertake it, but he is unable to devote himself continually to this sort of work, and it is more satisfactory to the persons concerned to conduct the required researches themselves. (*c*) A place where the bacteriological examination of waters and the investigation of the spread of various diseases could be performed. At present there is no means in the Presidency of getting this done, as it does not fall within the province of the Chemical Examiner. The source of an outbreak of cholera can only be conjectured, the advice given when typhoid appears in a family can only be suppositional, a suspicious diarrhœa has to remain suspected till it be possible to confirm preconceived notions by the aid of a miscroscope and cultures.

ABSTRACT OF THE REPORT OF THE MUNICIPAL COMMISSIONER FOR THE CITY OF BOMBAY FOR 1898-99.

(*W. L. Harvey, Esq.*)

Special Drainage.—In addition to 20 unfinished works in progress three new works were commenced, viz., (1) surface drainage works in Kamathipura district; (2) 41 manholes on the old ovoid sewers in Kamathipura; (3) works in 9-inch pipe sewer in the new roads on the southern part of the Apollo Reclamation and other roads.

Pumping Station, Love Grove, Worli.—The Worthington engines at this station continued to work satisfactorily. The efficiency of the pumps ascertained by fortnightly observations showed an average of 92·4 per cent. The gunmetal rams of No. 1 engine have been replaced by cast-iron rams. This is a tentative measure for economical reasons, being much cheaper than the gunmetal rams.

House Connections.—The street portions of house drainage connections were made to 1,381 houses, at a total cost of £2,654.

WATER WORKS.—*Tansa Lake.*—The rainfall for the year 1898 was 98·68 inches, that for 1896 and 1897 being 120·13 and 104·82 inches respectively. The heaviest fall of rain occurred on the 21st July when 4·05 inches were registered. The lowest recorded level of the water was 394·53 T.H.D. on the 9th June, 1898. The lake commenced to overflow on the 8th July after 31·52 inches of rain had been registered, and ceased to overflow on the 4th October, 1898. The storage above the lowest outlet on the 1st October, 1898, was 18,600 millions of gallons, and on the 1st April, 1899, it was 12,113 millions of gallons, showing a consumption of 6,487 millions of gallons in six months, or 35·6 millions of gallons per day, including evaporation and leakage; of this about 23·8 million gallons were delivered into the aqueduct. The quantity of water which passed over the waste weir is estimated at 25·198 millions of gallons. The highest flood level was 405·9 T.H.D. on the 21st July. The balance of water delivered at Ghatcooper syphon head is estimated at 7,873·1 millions of gallons. About 47·5 millions of gallons passed into the Vehar Lake as against 165 and 213 millions for the years 1896–97 and 1897–98 respectively. The amount is yearly diminishing owing to the increasing consumption of Tansa water.

Vehar Lake.—The rainfall for 1898 was 94·51 inches, that for 1896 and 1897 being 109·81 and 97·36 respectively. The heaviest fall occurred on the 22nd July, when 6·23 inches were registered. The lowest water level during the year was 252·80 T.H.D. on the 8th June, 1898. The overflow commenced on the 11th September and ceased on the 1st October, 1898. The waste weir stop planks were raised, thereby increasing the storage capacity by about 400 million gallons. The storage of water on the 1st October, 1898, was 11,767 million gallons, and on the 1st April, 1899, 8,940 million gallons, showing a consumption of 2,827 million gallons, including evaporation and leakage, but exclusive of that received from Tansa duct. This consumption covers a period of six dry months of the year. 47·5 million gallons were received from the Tansa overflow. The quantity of water that overflowed the waste weir is estimated at 2,300 million gallons. The filter beds worked regularly during the year and were cleansed on an average of every 10 days.

Tulsi Lake.—The rainfall for the year 1898 was 111·58 inches, that for the two previous years 1896 and 1897 being 139·52 and 118·66 inches respectively. The heaviest fall of rain occurred on the 22nd July and was registered at 9·84 inches. The lowest water level reached was 438·15 T.H.D. on the 10th June, 1898. Overflow commenced on the 24th July, 1898, and ceased on the 21st September. The storage on the 1st October, 1898, was 2,269 millions of gallons, and on the 1st April, 1899, 1,222 millions of gallons, thus showing a consumption of 1,047 millions of gallons. During

the six dry months of October to March this was inclusive of evaporation and leakage. The catch-water channel entering the lake at the south-west and was repaired and other necessary work done departmentally.

Pawai Lake.—Negotiations have been concluded between the Corporation and the Agave Fibre Syndicate to let the property for the cultivation of the Agave plant and its manufacture into fibre, and to supply water from the lake.

Bhandarwada Reservoir.—On account of the contractor not washing the sand for the filters in a proper manner, this portion of the work is being done departmentally. Filter No. 9 was put in use on the 14th February, 1899, and found to work satisfactorily, but the rate of filtration is practically reduced by one-fourth owing to a leak through the arching into the reservoir. The work of charging filter No. 8 is nearly complete. The filtering materials of No. 5 filter have been washed and replaced departmentally at a cost of £131. It is now working satisfactorily.

Malabar Hill Reservoir.—The sand in filters Nos. 2 and 3, which was the subject of a dispute with the contractors, has been washed and replaced departmentally at a cost of £158, of which £30 were contributed by the contractors. The filters are now working satisfactorily. It is proposed to extend the filter-beds, but experiments will first be made to ascertain the most efficient rate of filtration.

Miscellaneous Works.—The laying of the 9-inch main in Worli Road substituted for the 3-inch main was completed during the year at a cost of £2,841, and is now in use. The work of laying 4-inch cast-iron mains in various parts of the city at an estimated cost of £1,625 was completed on the 12th May at an expenditure of £1,518. The total number of lineal feet laid was 9,098.

A revised scheme for extension of mains in various parts of the city is the subject of inquiry by a committee of the Corporation.

Distribution and Maintenance.—The number of connections cut off during the year at the instance of the Executive Health Officer was 204, and to meet the necessities of the people 151 stand pipes were erected. The consumption of water continues to be excessive and was about the same as the previous year. The number of bursts during the year was 93 against 109 the previous year. The net increase in the number of connections, exclusive of those made for health camps, &c., has been 175 or 3·7 per cent. The total number now stands at 19,990. The number of meters in use on the 31st March, 1899, was 2,371, being an increase of 162 on that for the previous year. The consumption by meter for the year registered a little over 1,470 millions of gallons. For the preceding year the quantity was a little over 1,253 millions of gallons.

PUBLIC HEALTH.—The state of the public health during the year under review was unsatisfactory. The mortality was 4,065 more than in the preceding year. The total number of deaths from all causes amounted to 51,961, equal to a death-rate of 63·23 per 1,000 of population, calculated on a population of 821,764 (census of 1891). The average number of deaths for the previous five years amounted to 156,900, or a death-rate of 38·18 per 1,000 of population.

The number of deaths according to place of birth was as follows :—

Born in Bombay	15,479
Born elsewhere and unknown	33,733

The sections of highest mortality were Kamathipura 95·91, 2nd Nagpada 95·48, Byculla 88·68, Parel 81·48, Kumbharwada 79·54, Tardeo 77·08, and the sections of the lowest mortality were Water Division 2·25, Fort Southern 4·30, and Walkeshwar 20·01 per 1,000 of population. The death-rate was highest amongst Negro-Africans, Lingayets, Low-caste Hindus, Jains, Mussalmans, and Buddhists being respectively, 616·44, 159·43, 98·82, 84·04, 72·60, 63·15 per 1,000 of population, and lowest amongst Europeans, Jews. Parsees, Eurasians, Brahmins, and Native Christians being respectively 17·89, 36·84, 39·13, 45·26, 46·70, 47·28 per 1,000 of population.

Small-pox.—The deaths from small-pox were 55, being two less than in the preceding year. The rate of mortality was highest among Native Christians. The mortality was highest in 1st Nagpada, Water Division, Mahim, Worli, Sewri, and Mazagon.

Measles.—There were 254 deaths from measles, being 105 less than in the last year. Of these, 200 occurred in the first four years of life. The highest mortality was amongst Lingayets, Hindu low-castes, Jews, and Mussalmans. The death-rate was highest in 1st Nagpada, Khara Talao, Dongri, 2nd Nagpada, Kamathipura, and Byculla.

Fevers.—There were 4,114 deaths from fevers, being 2,837 less than in the last year. The death-rate was highest in the districts of Parel, Mahim, Kumbharwada, and Byculla. The greatest mortality was amongst Negro-Africans, Hindu low-castes, Mussalmans, and Native Christians.

Cholera.—The number of deaths from cholera was 104, being 1,161 less than in the preceding year. The sections of the highest mortality were Sion, Mahim, Dongri, Mahaluxmi, and Byculla, being ·35, ·27, ·26, ·23, ·23 per 1,000 of population. The highest death-rate by caste was among Native Christians, Jains, and Hindu low-castes.

Phthisis.—There were 5,624 deaths from phthisis, being 303 less than in the previous year. The death-rate was highest in 2nd Nagpada, Umarkhadi, Chakla, Kamathipura, and Khara Talao sections. The greatest mortality was amongst Negro-Africans, Lingayets, Mussalmans, Hindu low-castes, and Jains.

Leprosy.—There were 51 deaths from leprosy, being 12 less than in the preceding year.

Plague.—There were 18,185 deaths from plague, being 7,182 more than in the last year. Detailed particulars of this disease have been given by the Executive Health Officer in his report.

Births.—The number of births registered, exclusive of still-born, was 10,784, or 1,448 more than in the last year. Of these, 5,640 were males and 5,144 females. The diminution in the number was probably due to the exodus of people on account of the prevalence of plague. Excluding Negro-Africans, the birth-rate was highest amongst Hindu low-castes, Jews, Lingayets. The sections giving the highest birth-rate were Mahim and Sewri.

5926—6

ABSTRACT OF THE REPORT OF THE HEALTH OFFICER OF BOMBAY CITY FOR 1898.

(*Lieutenant-Colonel T. S. Weir, I.M.S.*)

Before examining the mortality, it is well to consider the position of Bombay. The portion of Bombay on which most of the population live in closely built houses and densely populated habitations lies in a valley between rocky ridges, the centre of the valley being in places below mean sea level; on the south side most open to the sea, and raised above the sea level by sand and alluvial deposits. Up the valley, between hillocks, at one time flowed creeks. These creeks and the hollows, over which the sea water spread, have been largely filled with vegetable matters which have not yet at depths decomposed. There is still underground an ooze where these creeks flowed, and the ground waters of the valley are influenced by the pressure of the sea currents around. The valley of Bombay is most unfavourably situated. Into it flows the rain water from higher lands, the escape of which is obstructed by roadways and buildings, and to the north by a dense clay formation. But happily the soil has a marvellous power of purification, even greater than the air. In the centre of the valley towards which most of the drainage flows the soil is a stiff clay.

The area of Bombay is about 22 square miles, and on a portion of this area there is the most densely crowded population in the British Empire, the six sections of greatest density of population having 227,021 people on an area of 403·28 acres.

In 1895, before the appearance of plague, Bombay was more healthy than any large city in India, and the chances of life were better than in many European towns. It is fervently hoped that this will be the last of this abnormal cycle of years. The Meteorological Reporter was of opinion, that the remarkable period through which India has passed had terminated, in 1897, and a period of normal conditions, he now thinks, is probable for two or three years.

The temperature of the air in April, May, June, July, August, September, October, and November was above the average. It is a curious and important fact that the ground temperature since 1896 has been rising at all depths, more or less, except in the cold season, being 84·8 in 1896, 84·9 in 1897, and 86·3 in 1898—5 feet below the ground in each year. The total rainfall for 1898 was 7·44 inches less than in 1897, and 13·56 inches less than in 1896.

There were observed during the year some meteorological phenomena of interest and deserving of notice. On the morning of the 6th of July there was a strong smell, as if sulphuretted hydrogen was generated, over the north of the island, and especially from the salt channels across Matunga and the vacant ground to the north. The smell seemed strongest furthest to the north. At this time a migration of rats had been observed across Sewree, and I believe the smell was due to the decomposition of dead rats, for a number of bodies of rats were afterwards found in the suburbs. The Commissioner of Police and I happened to go over the north of the island on this morning in connection with arrangements being made for the inspection of traffic by the roadways into Bombay, and we tried to ascertain the cause. The smell was most offensive, tainting the air far and wide. A blue haze was often observed in the evenings of September and October, and rainbows which I had not observed in Bombay for a long period. At this season boils were very prevalent. On the 9th of September a gale blew, and the sky looked like a monsoon storm. In the evening rain fell. A little time afterwards dead rats were found on the west foreshore. There were few mosquitoes seen during the epidemic period of 1898, and it seemed as if they had almost disappeared from the island. The disappearance of mosquitoes was again observed in August.

The epidemic gradually rose from the middle of December, 1897 (a little later than in 1896), till on the 9th February, 1898, a mortality of 347 was recorded, followed by a series of repressions and fluctuations till the 16th of March, when the mortality rose to 358, and again on the 18th of March to the same number, from which date the epidemic began to decline, and fell until in the middle of June and up to the end of August it descended

below the mortality in the corresponding month of 1897. From the end of June the mortality began to ascend till it reached its maximum in the second week of October and then fell, but not descending again to the curve of June, and again began to ascend in the first week of December. It has to be remembered that the total mortality from all causes was not as high as the mortality from plague alone in many cities in India. In 1896 the total mortality was only 40·71 per 1,000, in 1897 it was 58·28 per 1,000, and in 1898 it is not over 63·23 per 1,000.

The hopes that some sanguine people entertained, that it was only necessary to carry out a few sanitary measures, and the disease of plague would stop, have been grievously disappointed. We see now after three years of incessant activity against plague that the disease is more virulent and destructive in type than ever. It is not that the mortality is high after what has been done, but it is what it might have been, and it has to be considered what the mortality would assuredly have been, if the measures that have been carried out had not been taken. Whatever the period or whatever the measures, whether of the Health Department or of the Plague Committee, it is marvellous that the mortality has been so low, that the measures have saved so many lives; and equally marvellous that the city has suffered so little.

Such was the general course followed by the epidemic in 1898. The view I held was that the epidemic had been prolonged by the concealment of cases, and that the type was intensified by concealment.

As soon as I returned from leave in January, 1898, I wrote a report commenting on the progress of the epidemic, the measures of the Plague Committee, and the concealment of cases, and recommending certain measures.

The difficulties of obtaining information that beset the Plague Committee were very great. The type of disease, as in former years, was often difficult of recognition. There was a type similar to cholera, and there were types of disease in cases of which it was difficult, even with a bacteriological examination, to establish whether they were plague or relapsing fever. The Plague Commission had an opportunity of seeing one of these cases on their first visit to one of our hospitals. The case was supposed to be one of pneumonic plague with petechiæ, but bacteriological examination proved it to be one of relapsing fever. Cases began with ordinary fever; afterwards fever with symptoms like those of relapsing fever supervened, and finally plague developed.

It is scarcely necessary for me to discuss the policy followed in 1898, as the policy is now practically the same as the policy followed by the Health Department when plague first appeared. The policy of 1896 has been justified by events and by the visitations of the following years.

The experience of this year indicates that the measures enforced in 1898 did not produce better results than the measures adopted in the previous years.

On the 1st of June the city plague administration was taken over by me, and one of the first measures I gave attention to was *inoculation*. Already I had been busy opening stations for inoculation, and I had been with M. Haffkine to chawls, persuading the people to be inoculated, and we had a great measure of help and encouragement. I began, after taking over charge, a system of payment to the poor at the time of inoculation, and certainly it led to a great increase in the number of inoculations. M. Haffkine one morning with me vaccinated in one chawl as many as 45 people, 22 of whom were women. It was afterwards considered necessary to discontinue payment, and the desire for inoculations began to decrease owing to other causes and influences, the most serious effect of which was, not a spirit of opposition, but a want of faith. Inoculation to be successful must be encouraged at the right time. There is a fashion, and also a sentiment, as in everything human, which have to be taken account of. Taken at the right moment, numbers of people may be persuaded to be inoculated, who could not or would not be persuaded at any other time. Besides, there is not the fear of the disease in Bombay that exists in other places where the disease has been very destructive and fatal. It is necessary to the success of inoculation (1) that the local reaction and pain should be reduced, (2) that the operation should be performed with care and therefore slowly.

I think that everything that could be done to open inoculation stations, and persuade the people to be inoculated, was done after the municipality took over charge of plague measures. About 34 stations were opened, and of the 34 inoculating officers 13 were under the municipality. After June, when the municipality took over charge of the plague administration, M. Haffkine and other officers accompanied me to the houses of the poor to inoculate people; but there was not the dread of the disease which was necessary to help us to inoculate large numbers. We met with much encouragement. Frequent meetings were held in the city, at which the Municipal Commissioner, Mr. Harvey

was present, and the Commissioner formed a Committee, over which he presided, which sat every week in his office to deliberate on the progress of inoculation and to discuss the best measures to be adopted. I do not think more could have been done than was done in 1898 to bring inoculation within reach of the people, or to persuade the people to be inoculated.

The mortality from plague by class indicates that the classes most careful of animal life, and most engaged in the distribution of the grain supply, have suffered most. The low mortality amongst Mussalman must, I think, be ascribed to imperfect recognition. The mortality amongst Hindu low castes is almost the same as in 1897. The mortality amongst three classes, *i.e.*, Europeans, Eurasians, and Parsees, rises progressively from 1·32 amongst Europeans (almost the same as in 1897) to 7·39 amongst Eurasians, being 2·3 less than in 1897, to 10·28 amongst Parsees, being 2·7 more than in 1897. It is interesting that in this year of enhanced virulence and greater intensity the number of Europeans who suffered should be five less than in 1897.

The distribution by localities of the 18,185 deaths from plague is interesting, and follows nearly the same incidence as in former years. It is difficult to draw any exact conclusions from the recorded mortality by sections from plague. There was the difficulty of recognition or detection, and there was concealment influencing the registration of the disease. One of the sections of low mortality, 12·87 per 1,000, was Khara Talao, and yet this section is one of the most insanitary and overcrowded sections in the whole island. The other sections of low mortality are a portion of the Mandvi ward, Chuckla, and Umerkhadi. The distribution of mortality indicates either imperfect recognition or concealment in some sections. There are sections where the mortality must be low, but there are sections where, if the mortality is low, it cannot be correct. It is easy to place the finger on the localities of most concealment. The ward of highest recognised plague mortality is E Ward, which is therefore probably the ward of most detection.

In both sexes a greater enhancement of mortality was observed amongst those over five years of age than at an earlier period of life. It may be said that the disease is most difficult of recognition and most easy of concealment in those under five years of age, and therefore the enhancement over five years of age is due to more exact registration. The most susceptible periods are between 25 and 40 years.

The course of the mortality by dwellings is almost the same as in 1897, and illustrates the influence of ventilation, though it is not necessary to illustrate by statistics the influence of ventilation on the occurrence of cases any more. The mortality decreased with the height of the dwelling, being nearly 86 per cent. on the ground floor, over 77 on the first floor, 71 on the second floor, 61 on the third floor, 57 on the fourth floor, and 51 on the fifth floor. In 1897 the chances of recovery progressively increased from the first floor upwards, from a mortality of 84 per cent. on the ground floor to 45 per cent. on the fifth floor. In all wards there was the same progressive decrease in the fatality with the height of buildings.

While writing of the mortality by buildings and floors, I would draw attention to the remarks I made last year in regard to the recurrence of plague in buildings. It is, I believe, chiefly due to the existence in these buildings of attractive and favourite feeding and hiding places for rats. At first I thought the greater freedom of certain dwellings or the reduced incidence of plague in some buildings after the drainage had been improved was due to the effect of the improvement of house drainage, but afterwards I came to the conclusion that it was chiefly due to the closing and filling up of rat holes. Therefore, if it were practicable to improve house drainage, to clean and renew all down-take pipes, to properly construct or repair all house gullies and drains, it would have a great influence on the recrudescence of plague. I have in previous years given statistics showing the recurrence of plague by houses, and I have given evidence on the subject before the Plague Commission.

The mortality was highest in March and lowest in June. The most rapid development and spread of the disease occurred in February, the deaths rising to 348 on one day. In February the number of cases rose to 5,351 from 3,654 in January, of whom nearly 84 per cent. died. In March there was a further rise to 5,764 cases and an increase in the mortality to 86 per cent. In April the cases fell to less than one half and the mortality declined, being equal to nearly 80 per cent. The highest mortality for any one day was 358 on the 16th of March, and again on the 18th, when it was the same number. The disease decreased a little after the middle of March, and the decline became rapid towards the end of the month, and reached its minimum by the end of June. A recrudescence began towards the end of July, and reached its maximum in October, followed by a

further recrudescence in the middle of December to develop into a greater epidemic than known before.

General Mortality by Causes.—The highest mortality from any one death cause is referred to plague, being 22·12 per 1,000 against 13·3 per 1,000 in 1897. Concurrently with the increase in the mortality from plague there was an increase in the mortality from diseases of the respiratory system, but a considerable decrease in the mortality ascribed to phthisis and fevers. The chief death causes that contributed to the high mortality are plague, diseases of the respiratory system, and phthisis.

TABLE SHOWING THE NUMBER OF DEATHS AND THE DEATH-RATE FROM THE PRINCIPAL CAUSES DURING 1898.

Cause of Death.	No. of Deaths.	Death-rate per 1,000 of Population.
Small-pox	55	·06
Measles	254	·30
Fevers	4,114	5·00
Cholera	104	·12
Phthisis	5,624	6·84
Plague	18,185	22·12
Diseases of the Nervous System	2,577	3·13
Do. Respiratory System	8,423	10·24
Diarrhœa	1,800	2·19
Dysentery	1,585	1·92
Accidents	559	·68
Other and unknown causes except still-born	8,681	10·56
Total	51,961	63·23

The mortality rapidly rose in January through February until a maximum was reached in March. The highest mortality was registered in March, being 9,196 deaths. A recrudescence began in August, developing into a monthly mortality of 3,507 in October.

The incidence of the mortality by place of birth indicates even more stongly than the statistics of last year, that the chief sufferers from plague in the population are strangers. In 1897 a total of 16,191 persons born in Bombay and 30,579 born elsewhere died. In 1898 the mortality amongst strangers is even more in excess—33,733 died and only 15,479 of the people born in Bombay. The course of the epidemic is well indicated by the mortality amongst the people born outside of Bombay. Through January and February the mortality rose till it reached its maximum in March. A progressive decrease followed till July, when a further recrudescence occurred, which subsided in or about November to revive again in December.

Notwithstanding the high mortality of the year, the death-rate of Europeans was only 17·89 per 1,000, lower than in the previous and many other years. The total death-rate amongst Europeans in 1898 is lower than in any year since 1893! This is a very remarkable protection from disease during a year of plague. Yet Europeans did not flee, and many of them approached the sick and exposed themselves fearlessly in aid of the suffering. The Mussulman mortality is also lower than in 1897. The mortality amongst Jews was under 37 per 1,000 and amongst Parsees 39·13 per 1,000. The mortality amongst Parsees is 6·5 per 1,000 higher than in 1897. Excluding small communities, the highest mortality occurred amongst the mass of the Hindu population, being equal to 93 per 1,000. Mussalman, a large community, have the next highest mortality, the death-rate being as high as 72·60 per 1,000.

If the mortality of the classes is examined according to sex, it will be observed that the mortality of the communities amongst whom the death-rate was highest was influenced by a high fatality and great loss of female life. Take, for instance, the mass of the Hindu low caste population, the excess of female mortality was equal to 11 per 1,000 and amongst Mussalman as much as 22·6 per 1,000. If we take the classes of low mortality, it will be observed that the excess of female mortality is not great. Amongst Parsees it is 2·8, amongst Jews 3·5, and amongst Europeans 7·2. The plague death-rate of Europeans was only 1·32 per 1,000, the attacks being 20 and the deaths 15, out of a total population of a little more than 11,000 Europeans.

The mortality of females is 10·66 in excess of the male death-rate. The mortality amongst males was highest under one year of age, and descended till the period of life

between 15 and 19 years of age, and again rose from 20 to 24 years. The female mortality followed almost the same incidence as that of the male. But the excess female mortality is less than in the years preceding the appearance of plague. The female mortality is almost the same as in 1897, and the excess mortality of the year is amongst males.

As in 1897, the mortality in some of the most crowded sections is relatively low. It is also very remarkable that in some sections in this year a comparatively low mortality has been recorded, notwithstanding the epidemic of plague, and notwithstanding the apprehensions that have been felt. In the Fort South, the death-rate was only a little over 4 per 1,000. In a favourite locality, such as Walkeshwar, the death-rate may be expected to be low, and it will be observed that it is only just over 20 per 1,000. In the Esplanade, a locality in the distribution of its population not unlike Walkeshwar, it is only 24 per 1,000. In the suburb of Sion the mortality is only 36 per 1,000, but in the great section of Fanaswady the mortality is not higher than 48 per 1,000. In the densely populated section of the Market the mortality is under 50 per 1,000. In some of the suburbs the mortality is higher than in the most densely populated localities. This is partly due to the movement of the population from the city to the suburbs. But it is also greatly due to other reasons which have been discussed at length in previous reports.

Cholera and Famine.—Amongst the ill-fed during years of famine or scarcity the famine types of disease may be expected ; and though with a better year than in 1896 and 1897 the immigration of the destitute was less, there were a large number of people who, if not famished, were in ill-health from poor food and wretched lodging. In the last report I drew attention to the fact that, synchronous with the prevalence of cholera in this city during the monsoon, the disease was epidemic in the country around. The mortality from cholera this year is small, only 104 deaths were registered, being 1,161 less than 1897 and 380 less than the average. The mortality declined progressively in the first three months of the year, and later only three deaths were registered in June ; but in July there was a slight increase.

The sections of highest mortality were Sion, Mahim, Dongri, Mahaluxmi, and Byculla. Excepting one section, the northern suburbs were most affected. In 1897 the same incidence was observed. The distribution of mortality by class shows that the Native Christians had the largest number of cases, and following them, Hindus. The mortality by sex indicates that the disease fell heaviest on males, the male death-rate being ·15 per 1,000, and the female ·07 per 1,000, although the percentage of deaths to attacks among females is slightly higher than that of males. The mortality by place of birth is very striking ; whereas there were only nine deaths of persons whose birth-place was Bombay, there were 95 deaths of persons whose birth-places were outside Bombay.

Fevers.—From fevers 4,114 deaths were registered, being 2,837 less than last year and 2,772 less than the average. Of the deaths from fevers, 3,716 were referred to remittent fever, being 2,188 less than in 1897 and 1,957 less than the average. 259 deaths were ascribed to simple fever, being 530 less than in 1897 and 652 less than the average. To ague 102 deaths were referred, being 123 less than in 1897 and 170 less than the average. To enteric fever 37 deaths were referred, being four more than in 1897 and seven more than the average. The mortality from fevers did not follow the same incidence as in 1897. In that year the mortality from fevers decreased in the first half of the year as the epidemic of plague declined, and again increased in the rains with the revival of plague. It will be remembered that through the monsoon of 1897 there was a serious increase in the mortality from fevers concurrently with the prevalence of cholera. In 1898 the increase during the rains concurrently with the recrudescence of plague was observed later, and proved to be much lower. Taking the whole the year 1898, the fluctuations in the mortality from fevers were much lower than in 1897. The highest mortality was registered in March, and the lowest in the second month of the rains in July. The investigations of Ross on the conveyance of malarial organisms by mosquitoes suggests to us the necessity of studying the mosquito life of this island. The part played by the mosquito suggests also an explanation of the fluctuations in the district mortality.

There were, however, great fluctuations observed in the mortality from fevers in different months in some classes. In April the mortality from fevers amongst low-caste Hindus rose from 1·3 per 1 000 in March to 8·2 per 1,000 in April, and remained high till November. The mortality amongst Mussulman decreased in April and continued to decline till August. The mortality amongst Parsees reached its maximum in February

and did not rise again during the year. The mortality amongst Europeans was very low in January, and in February and March there were no deaths; but in April and May the mortality rose, to decline in June. It ascended in July and August and descended in September, to rise again in October. There were no deaths in November and December. In this year, as in 1897, the mortality amongst Brahmins is low. The mortality by class fluctuates between 1·7 amongst Europeans and 6·9 amongst Hindu low-castes. The mortality of Mussulman is lower, and the death-rate among Parsis is a little above that of Europeans.

The highest mortality from fevers occurred in Parel, Mahim, Kumbharwada, and Byculla. As in 1897, the mortality in some of the most crowded sections is less than in the suburbs. Except in one suburb, Sion, the mortality in all the suburbs is above the average. I believe the part played by the mosquito in the communication of fevers will be found to be the explanation of this incidence of fevers in localities.

A total of 546 deaths was registered from relapsing fever. There were two recrudescences of the disease during the year—one in the cold season attaining its maximum in March, and the second attaining its maximum in the rainy season in October, the maxima periods of intensity corresponding with the maxima periods of intensity of plague. In the Arthur Road Hospital 1,581 cases of relapsing fever were admitted, of whom 329, or 20·8 per cent., died. It is well to contrast this mortality with the death-rate of 73·25 from plague, which was nearly 7 per cent. higher than in 1896–97.

Measles.—From measles 254 deaths were registered, being 105 less than in 1897 and 190 less than the average. The distribution of the mortality follows nearly the same course as in former years, being highest among the Hindu low-castes of all large sections of the population. The death-rate amongst Jews comes next, followed by the mortality amongst Mussalman. As in preceding years the mortality amongst females was higher than amongst males, the death-rate amongst females being ·44 per 1,000, and males ·22 per 1,000.

Phthisis.—From phthisis 5,624 deaths were registered, being 303 less than in 1897 and 1,372 more than the average. The mortality follows the same incidence, in spite of plague, as in former years. In each year it has testified to the great loss of life caused by seclusion in crowded and ill-ventilated dwellings. The same sections in this year as in the past are sections of high mortality. The sections of ill-repute for this disease are—2nd Nagpada, Umarkhadi, Chuckla, Kamathipura, Khara Talao, and Byculla. Byculla has this year, with an increasing population, displaced Bhuleshwar. These are the sections to which the attention of the Improvement Trust has been drawn, and it has, as I know, been already given to them, and surveys have been made. What is wanted in all these sections is more ventilation of building and more ventilation of locality. There are too many houses and people. The number of houses must be reduced, and the number of rooms in the houses that are left must be fewer. The reduction of mortality, as compared with 1897, is due to a lower death-rate amongst females, the number of deaths of females being 2,940 against 3,075 in the last year. But though there is a reduction in the total female mortality, the mortality amongst females is yet very nearly double that of males. This great tax of disease falls on Mussulman and some high-class Hindus. In the mass of the poor Hindu population, in spite of the laborious lives of the women, the mortality is less than half the loss of life of Mussulman. There is a decrease of 173 in the mortality amongst Mussulman, but I think this must be chiefly ascribed to a decrease in the female population. The decrease in the mortality from phthisis indicates one of two things, *i.e.*, either that there had not been great concealment of plague, or that the phthisical population had been reduced by plague. Both amongst males and females the mortality rose after 10 years of age, as was observed in 1897. In the period between 10 and 14 the first great divergence in the mortality between males and females occurs. This is the period when women come under the conditions that most favour the communication of phthisis. At this time of life the female mortality is more than three times the male death-rate.

Small-pox.—During the year only 55 deaths were registered from small-pox against 57 in 1897. Of the deaths from this disease 36 occurred amongst the mass of the Hindu population, and 11 amongst Mussulman. As in the previous year, when the disease was not epidemic, it was most prevalent in certain sections, which are insanitary and have a large proportion of unvaccinated. The mortality at age periods was highest under five years of age.

Diseases of the Respiratory System.—From diseases of the respiratory system 8,423 deaths were registered, being 566 more than in 1897 and 2,885 more than the average. Of the deaths from diseases of the respiratory system, 4,458 were referred to bronchitis, being 372 less than in 1897 and 1,136 more than the average. To pneumonia 1,370 deaths were referred, being 38 more than in 1897 and 20 more than the average. To whooping cough 182 deaths were registered, being 99 less than in 1897.

Births.—10,784 living and 1,569 still-born births were registered, being 1,448 more than in the last year. Of the living births 5,640 were males and 5,144 were females. The proportion of males to females by the census of 1891 was as 170·60 to 100, and assuming that there were 100 females to 100 males, the birth-rate would be equal to 22·38 per 1,000 of population. The decrease in the birth-rate, which has been observed in the areas affected by plague, is a phenomenon that must be anticipated from a study of the historical events that have marked all plague epidemics. It is a phenomenon so constant in plague epidemics that, had it not been observed in Bombay, the birth registration must have been condemned as untrue. The birth-rate in Bombay, assuming that there are 100 males to 100 females, was equal to 32·55 in 1895 to 32·97 in 1896, to 19·38 in 1897 and 22·38 in 1898. Had the birth-rate been of nearly nominal rate in 1897 and 1898 it would have been due either to incorrect registration or to an extraordinary immigration of women.

APPENDIX.

No. 1.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner with the Government of India for 1898.

The weather during 1898, according to the meteorological summary given in the first section of the Report, was quieter and more settled than usual throughout the whole year, and in most months was drier than the average. From March to May was unusually hot and dry in most parts of the country, and the mean humidity for the whole of India for the year was slightly below normal. The mean cloud amount of the year was 0·2 below normal: all periods of the year, except the monsoon period, had less cloud than the average. The rainfall of the whole year for the whole of India showed a variation from the normal of 0·43 inch in excess, as compared with variations in defect of the normal of 0·15 inch in the previous year, of 4·83 inches in 1896, and of 2·19 inches in 1895. In the cold weather period the rainfall was abnormal in its occurrence and distribution, scanty and in defect in January, and general and widespread in February. For the whole cold weather period the total was generally in excess. March, April, and May were all abnormally dry months over India, but in parts of Burma the rainfall during this period was above the normal. The monsoon commenced slightly later than usual along the West Coast, but the humid currents extended rapidly into the interior. The Bombay current was weak in August, and the rainfall scanty, but in September and October conditions were fairly normal. The rainfall of the last period of the year, November and December, was slight and scanty, except in Madras, where it was generally excessive. To what extent the public health was affected by the weather conditions, thus slightly sketched, it might not be easy to say; but the records of vital statistics show that the year was characterised by lessened mortality from malarial fevers and bowel complaints, and by a marked decrease of epidemic cholera and small-pox.

2. The average strength of the *European Army of India* was 67,741, or slightly less than that of the previous year. As measured by the ratios of admissions into hospital, constantly sick, and deaths, the health of the Army was better than in the previous year; but the ratio of invaliding was higher, and the total loss from deaths and invaliding combined was greater than in the previous year. Compared with those of the decennium 1886–95, the results are in all particulars, except in respect of admissions into hospital, unfavourable to the year under review; the constantly sick increased from a ratio, per 1,000 of strength, of 83 to 90, the deaths from a ratio of 15·16 to 20·05, and the invaliding from a ratio of 24 to 38; whilst the total loss, from deaths and invaliding combined, increased from a ratio of 39 to 58. The chief causes of admission into hospital were, again, ague and venereal disease; the former accounting for a ratio of 394·0, and the latter for a ratio of 362·9 admissions, per 1,000 of strength. The ratio of admissions from ague was nearly the same as in the previous year, but that from venereal disease decreased by 124·8 per 1,000 of strength. From ague and venereal disease combined, the ratio of admissions decreased from 882·4 in the previous year to 756·9 in the year under report, but still formed considerably more than half the total ratio from all causes. Ague, of itself, caused 27 per cent., and venereal disease 25 per cent. of the total admissions from all causes.

3. The diseases responsible for the greater proportion of the admissions took but a small share in causing the mortality for the year. Ague is credited with a death-rate of only ·30 per 1,000 of strength; and Table I. records no death as directly due to venereal disease. On the other hand, enteric fever, against which is recorded an admission rate of only 36·9, caused a death-rate of 10·17, or more than half the total death-rate of 20·05 for the year. Next to enteric fever, as causes of mortality, came abscess of the liver with a death-rate of 1·52, and heat-stroke with a death-rate of 1·17. The combined mortality from these three causes—enteric fever, abscess of the liver, and heat-stroke—was equal to 65 per cent. of the total mortality for the year. From no other one disease did the ratio of mortality reach 1 per 1,000 of strength—dysentery with a ratio of ·78, and pneumonia with a ratio of ·61, having been the next most fatal.

4. But, although the diseases chiefly concerned in causing admissions into hospital take a very subordinate place as causes of mortality, they again resume their foremost place in the list of causes of invaliding. Of a total number of 2,580 men invalided during the year, ague was accountable for 464, and syphilis and gonorrhœa for 569. The other chief causes of invaliding were affections of the circulatory system, debility, dysentery, and tubercle of the lungs. During the previous year the number of men invalided on account of secondary syphilis was 611, and during the year under review 547.

5. Of the four *Commands*, that of Madras was again the healthiest, as measured by the ratios of admissions and of deaths; whilst the Punjab Command, judged in the same way, was the most unhealthy. The ratio of admissions into hospital, per 1,000 of strength, in the Madras Command was 1292·6 as compared with 1558·0 in the Punjab; whilst the death-rate in the Madras Command was only 8·59, or less than a third of that recorded for the Punjab Command. Of the other two

Commands, the ratios of admissions and deaths in Bengal approached the closest to those of the Punjab; and the ratios in Bombay the closest to those of Madras. The Punjab was the only Command less healthy than in the previous year. In this last Command were recorded the highest ratios of deaths from cholera, enteric fever, malarial fevers, heat-stroke, pneumonia, and other respiratory diseases, and dysentery. Exposure, and the subsequent effects of exposure, to the contingencies of field service doubtless contributed to raise the admission and mortality ratios amongst the troops in the Punjab Command. The Tirah Field Force, which was broken up on the 9th of April, and out of which was formed the Khyber Force, "suffered heavily from enteric fever," as did likewise the Malakhand Force. Cholera was everywhere in comparative abeyance, only 14 deaths having been caused by it during the year. The outbreak of the disease at Umballa was the most severe, resulting in 10 of the total of 14 deaths. Pneumonia, as usual, was more fatal in the Punjab than in any of the other Commands. In none of the latter did the mortality-rate from this disease reach half of that recorded in the Punjab; in Bengal it was the lowest of all, reaching to less than a fifth of that in the Punjab Command.

6. According to *Geographical Groups*, the Gangetic Plain recorded the highest constantly-sick rate, and the Hills group the lowest; whilst the Indus Valley recorded the highest admission and highest death-rates. The Western Coast group, as usual, records low rates of sickness and mortality; but of all the groups those of Burma give the lowest death-rates for the year. The percentage of enteric fever to total admissions was greatest in hill stations, and this was also the case with regard to pneumonia and diarrhœa. In half of the other geographical groups the death-rate, from all causes combined, was less than the death-rate in hill stations from enteric fever alone.

7. The *stations*, with garrisons of upwards of 1,000 of strength, which returned the highest death-ratios were Peshawar and Quetta, the former recording a ratio of 48·95, and the latter of 44·43. Next to these two, but at a long interval, follows Lucknow with a death-ratio of 30·66. In all of these three stations enteric fever caused the largest proportion of the total death-rate. In Quetta the enteric death-rate was no less than 35·08 per 1,000 of the strength of the garrison, in Peshawar 24·48, and in Lucknow 22·57. The mortality rates in these three large garrisons in Upper India contrast strikingly with the rates recorded in three stations, with garrisons of about equal strength, in the Deccan and Southern India. In Secunderabad the total death-rate from all causes was 10·82, in Bangalore 10·64, and in Poona 9·45. It should be noted, however, that the health statistics in several of the stations in Northern India, including Peshawar, Rawalpindi, and Umballa, "are said by the medical officers to have been unfavourably "affected by the return or reception of broken-down men from frontier field service."

8. Beginning with the health statistics of the European Army of India, as a whole, the Report deals with them successively according to Commands, geographical groups, stations, and, finally, regiments. Of these last, the infantry had, as in the three preceding years, the highest admission and constantly-sick rates; whilst the cavalry had the highest death and invaliding rates. The regiment which recorded the highest death-rate was the 2nd Battalion of the Yorkshire Regiment at Peshawar. This regiment lost by deaths a ratio of 64·38 of its strength. Enteric fever was accountable for no less than 52·9 of this high ratio.

9. *Principal Diseases.*—There was a recrudescence of *influenza* during the year. The number of attacks was more than double the number in the preceding year, but fell short of that recorded in 1896. The season of greatest prevalence included, as usual, the months of March and April. Although only a single death was attributed to the disease, yet, in India, as in England, the prevalence of influenza affected, in a marked degree, the mortality ascribed to pneumonia and other respiratory diseases.

10. The European Army of India shared in the comparative immunity from *cholera* which characterised the year in India generally. Only 17 admissions, with 14 deaths, were recorded as due to this disease. The only station in which it prevailed in epidemic form was Umballa. In that station 11 Europeans were attacked, and only one of them recovered. It is worthy of remark that, of the 259 attendants on the 106 cases of cholera among Europeans and Native troops and among prisoners, not one contracted the disease. In connection with the Umballa outbreak, the only sanitary defect noted as likely to have been connected with the occurrence of cholera, was the liability of the water supply to contamination. If contamination of the water actually did take place, and was the cause of the outbreak of cholera, the question naturally comes to be asked why, out of a garrison of 1,896 men, presumably using the water-supply, all except 11 escaped attack. The movement of European troops in the seven instances in which this was resorted to was successful. "No attack occurred after movement, the effect of which on the general health was satisfactory."

11. Of *small-pox* mortality there was an entire absence; there were only two cases of the disease, with no death, against 24 cases, with four deaths, in the previous year, and against 122 cases, with 10 deaths, in 1896.

12. The ratio of admissions due to *ague* and *simple continued fever* was much the same as in the previous year. The admission-rate due to *remittent fever* in the year under report was 33 per 1,000 of strength, as compared with 25 in the preceding year, and with an average of 9 in the decennium 1886–95. The ratio of deaths from intermittent and remittent fevers was, however, lower in 1898 than in the previous year, although somewhat higher as regards simple continued fever. As in previous years, some of the medical officers differ as to where the line should be drawn between simple continued fever, ague, remittent fever, and enteric fever. "In the Cherat, Madras, Bellary, and Mandalay reports it is noticed that the relative numbers of cases of simple continued fever, ague, remittent fever, and, it might have been added, enteric fever, vary with a change of medical officer; and the medical officer of Bellary illustrates this by indicating his opinion that simple continued fever is no doubt of malarial origin."

13. The subject of *enteric fever* is dealt with at great length in the Sanitary Commissioner's Report. Of the 58 pages of Section II. devoted to a history of the health of the European Army of India, all except 19 are taken up with an account of the latest views held on the question of the etiology of the disease, followed by a description, shortened from the reports of medical officers, of some of the outbreaks among the troops during the year. The importance of the question of the causation and prevention of this most fatal of all the diseases to which the European Army of India is liable, might justify the devotion of even greater space to its consideration and discussion; but, unfortunately, neither recent research, nor the careful observations of the medical officers whose opinions are recorded in the report, seem to add much to what is already known regarding its origin and mode of spread. If results may be taken as any measure of the progress being made in knowledge of the disease, the record of another year's mortality is not encouraging. Enteric fever caused 445 deaths in the European Army of India in 1896; in the following year the number rose to 556; and now, in the year under report, it is 654. In each of these three years the death-ratios have been, successively, from 1896 onwards, 6·31, 9·01, and 10·17, per 1,000 of strength. A perusal of the account given in the report of the various theories and opinions held regarding enteric fever, is apt to produce a sense of bewilderment and uncertainty. Formerly, there was always the "solely water-borne" causation theory to fall back upon; but this exclusive view is now considered by a growing number of observers to be no longer tenable. One medical officer writes:—"It is to be hoped that the time is at hand when sanitary authorities will give their attention to some fresh point of the enteric problem, and leave the unfortunate water in peace for a time." It is acknowledged to be a common experience that enteric fever not infrequently prevails among troops using a water-supply pronounced by scientific experts to be pure and free, as far as they can ascertain, from the enteric *bacillus*; whilst, on the other hand, troops using water in which the *bacillus* is detected, often escape attack. There is already no want of suggested, or suspected, sources of infection to supplement, or take the place of, the part which water alone has hitherto been believed by many to play in the causation of enteric fever. At Quetta, the disease prevailed with greater virulence in the year under report than in any other station in India. There, "the catchment area is an ideal one, and the water above suspicion." As the result of his investigations in the cause of the fatal outbreak at that station, Major Davies, R.A.M.C., writes:—"If this reasoning be admitted, there can be no hesitation in believing that the epidemic prevalence of enteric fever at Quetta has been to a great extent of aërial origin, due to the situation of the trenches (for night-soil) to windward, and the omission to cultivate the ground." Among other possible means by which the disease may be communicated, are mentioned sick-room infection, flies, and inhalation of sewer air—the last of these suggesting revival of an old opinion. Native servants are considered by some medical officers to be media of infection; but seeing that natives are themselves immune from enteric fever, it is not very clear how they communicate the disease to others. Even the *bacillus* of *Eberth* seems of late to be in danger of being deposed from the place hitherto assigned to it of being the *causa causaus* of enteric fever. The differentiation of this *bacillus* from the *bacillus coli*—the latter an inhabitant, under ordinary conditions, of the intestine—is not always a simple matter. One medical officer writes:—"I am inclined to believe that what is known as enteric fever in India can be caused by the *bacillus coli*." Hankin's theory of "attenuated microbes" might afford some explanation of those cases in which the typhoid microbes are introduced into the body without producing infection. He says:—"My finding typhoid microbes in a water-supply gives no proof that the microbes were there present in a condition in which they could produce infection." But, tempting although the subject is, it cannot be followed further without laying this memorandum open to the charge of undue length, which we are sometimes inclined to prefer against the reports we have to deal with. Enough has perhaps been said to indicate the condition of uncertainty in which our knowledge, for practical purposes, of the cause of this terribly fatal scourge of Europeans in India still remains. Possibly, when the medical history of the war now being waged in South Africa comes to be written, some additional light may be thrown on problems connected with the origin and spread of enteric fever which are at present obscure.

14. The history of *plague* during 1898 seems to show that, unless European troops are placed under conditions which oblige them to expose themselves to the risk of infection, the chances of their contracting the disease are few. Only nine cases of the disease are recorded amongst them during the year, and of this number only two were fatal. Of the nine men attacked, all except three had been employed on plague duty. One of those attacked had been inoculated against plague in April of the previous year, and contracted the disease in the following January. The medical officer at Bangalore, where two of the cases occurred, writes:—"Inoculation and re-inoculation were performed in the case of the native followers of all British corps. To my mind this step appears to have had little practical effect, as the cases continued to be reported as regularly, and at about the same rate after inoculation as before. The step that really seems to have had most effect was the evacuation of the lines occupied by the followers of the various corps."

15. *Tubercle of the lungs* caused 37 deaths. "Much of the tubercle of the European troops is no doubt contracted in England." The ratios from all forms of tubercle disease taken together were highest in prisoners and next in European women; and these same had the highest and the next highest ratios from tubercle of the lungs. In these facts may, perhaps, be found support for the opinion now obtaining that an open air life is that most conducive to the prevention and cure of consumption. At any rate, there can be little doubt that, of the communities between which comparison of relative liability to the disease is here made, prisoners and European women in India generally pass less of their time in the open air than do the men of the European and Native armies. In an Appendix to Section X. of the Sanitary Commissioner's Report is given a "Report on the recent Congress on Tuberculosis at Berlin, with special reference to the Prevalence and Prevention of the Disease in India; by Alexander Crombie, M.D., Delegate for India." This extremely interesting and instructive report will repay perusal.

16. The sickness and mortality from *pneumonia* in the European army of India remain remarkably constant from year to year. There were 38 deaths attributed to this cause, giving a ratio practically the same as that recorded in each of the two previous years. The Indus Valley was, as usual, the geographical group in which pneumonia was most prevalent.

17. *Abscess of the liver* was responsible for 102 deaths, giving a ratio, per 1,000 of strength, of 1·52 as compared with a ratio of 1·29 in the previous year, and of 1·13 the average during the period 1886–95. A table is given showing that the mortality from abscess of the liver was 25 times greater among European than among Native soldiers. Among the 102 fatal cases, 48 were associated with dysentery or ulceration of the intestine. Of *dysentery* and *diarrhœa* there was a marked decrease in the number of admissions and in the number of deaths; these, as stated in the report, having in fact fallen to normal after the unusual elevation of the preceding year.

18. The admission-rate from *venereal disease* was 362·9 per 1,000 of strength, against 485 in the previous year, and 511·6 in 1896. As the Sanitary Commissioner puts it, there were in 1898 for every 1,000 men, nearly 123 fewer admissions to hospital for venereal disease than in 1897. But the remark that immediately follows shows this decrease to have been "partly unreal, and due to the widespread adoption of the system of treating venereally-affected men as out-patients." On the other hand the decrease was "partly real, and due to continuous and more prolonged treatment of the sick, to measures adopted under the new cantonment rules, to the placing of certain bazaars and cities out of bounds on account of the plague, and to the employment of a certain number of men on field service." When, however, it is recorded that the number of deaths directly due to venereal disease fell from 23 in the preceding year to 17 in the year under report, and the number of invalidings from 662 to 569, it cannot be denied that, whatever of *unreal* decrease the figures may conceal, there was also a decided and welcome balance of *real* decrease. The Madras Command had the lowest ratio of sickness due to venereal disease, and the Bengal Command, as usual, the highest.

19. The health of the *Native army*, with an average strength of 126,036, was, like that of the European army, better than in the previous year. The admission rate fell from a ratio of 839 per 1,000 of strength in 1897, and from an average of 976 in the decennium 1886–95, to 816 in the year under report, and was, as usual, much below the admission-rate recorded for the European army; this latter, as stated elsewhere, was 1,437. The constantly-sick rate in the Native army showed no decrease, but, on the contrary, rose from 31 to 33 per 1,000 of strength: it was still, however, greatly below the rate for European troops, which was 91. The death-rate from all causes, including the deaths of men absent from their corps, decreased from 14·90 to 13·33, and was 6·72 below the European army death-rate. As heretofore, ague was the chief cause of admission into hospital, and pneumonia the chief cause of mortality. Ague was, of itself, the cause of 41 per cent. of the total number of admissions, or of exactly the same percentage as in the previous year. Pneumonia was more fatal than in 1897, the death-rate caused by it rising from 2·73 in that year to 3·77 in the year under report: it thus caused no less than 34 per cent. of the total deaths. In agreement with the general condition of abeyance in which it remained throughout India during the year, cholera was also less fatal in the Native army—the death-rate from this cause falling from ·52 in 1897, and from a decennial average of 1·32, to ·33 in the year under report. Remittent fever caused 10 per cent. of the total number of deaths. Between them, pneumonia and remittent fever were responsible for 44 per cent. of the total mortality in the Native army. The loss from invaliding offers a strong contrast with that recorded for the European army. In the latter, 2,580 were invalided: in the Native army, of nearly double the strength, the number was 1,772. In the Native, as in the European army, intermittent fever and anæmia and debility caused a large proportion of the invaliding. In the former, 563 of the total invalidings were due to these causes, and in the latter 646. But whilst in the European army the invalidings due to venereal disease numbered 547, in the Native army they numbered from the same cause only 99.

20. According to *Geographical groups*, the Native troops stationed in the North-West Frontier and Indus Valley group give the highest ratio of admissions into hospital, and those stationed in Southern India the lowest—the former of these two groups with an admission ratio of 1119·0 per 1,000 of strength, and the latter with an admission ratio of 635·4. But Assam returns by far the highest death-rate, whilst the Gangetic Plain group gives the lowest; in the former a death-rate of 27·15 is recorded, and in the latter, one of 4·98. The Native troops in Assam suffered very severely from cholera, a ratio of 8·40 deaths from this cause alone having been recorded, and of 3·88 from dysentery. The Upper Sub-Hymalaya, Hill Stations, and North-Western Frontier and Indus Valley groups had the highest death-rates from pneumonia—each of them returning, in the order above mentioned, rates of 4·55, of 5·39, and of 9·04 per 1,000 of strength. Certain of the large stations record very high death-rates among Native troops. In Edwardesabad the death-rate for the year was 40·61, and in Datta Khel 40 32. The principal cause of death at both places was pneumonia, the former station recording a death-rate from this single disease of 29·89, and the latter of 31·36.

21. The upper of the two tables on page 87 of the Report well shows the uniformity with which each year of high *influenza* prevalence in the Native army is followed by a year of diminished prevalence of that disease; and also that, on the whole, since the great epidemic of 1890, there seems to be a tendency of both the maximum and minimum number of admissions to diminish during the years of increased and diminished prevalence which follow each other with more or less of regularity. The second table on the same page of the Report shows that "in 1898 the Native troops, with exactly the same admission-rate as the European troops, were, as usual, much less severely affected than the prisoners." The disease in the Native army was mostly of a mild type, only four deaths having been returned as directly due to it.

22. *Cholera*, *small-pox*, *ague*, and *intermittent fever* were all, excepting the last, less prevalent than in the preceding year. The greatest number of deaths from cholera occurred in Southern India and Assam, at Trichinopoly and Manipur. Of small-pox there were 26 cases with 1 death, against 53 cases and 6 deaths in 1897. The admission-rate from ague decreased from 347 to 335 per 1,000 of

strength. On the other hand, both the admission and the death rates from remittent fever rose—the former from 15·9 during the previous year to 20 in the year under report; and the latter from 1·04 to 1·08.

23. The remarkable contrast hitherto noted between the two armies, as regards their relative liability to *enteric fever*, repeats itself in the record of the year under review. Whilst in the European army the admission-rate was 36·9 of strength and the death-rate 10·17, in the Native army the former was only ·3 and the latter ·13. In the whole Native army of India 40 cases with 17 deaths were returned as enteric fever, against 51 cases with 15 deaths in 1897. But when it is added that "in not a single case does a *post-mortem* seem to have been obtained," there may be room for doubt as to whether all of the deaths were due to genuine enteric fever. That exact diagnosis is no easy matter in some cases may be concluded from the following remark:—"Two medical officers fear that, owing to the difficulty of diagnosis, they did not return all the cases that occurred in their regiments, having classed them as remittent fever, &c." The Sanitary Commissioner truly observes that, for the opinion that natives of India are apparently exempt from enteric fever only because they have already passed through the disease in infancy, has not yet been advanced the evidence of observed facts. On this question we have shown, in another *memorandum*, that such statistics as are available, and can be relied on, lend no support to the theory that natives are rendered immune from attacks of enteric fever owing to their having suffered from the disease during their childhood. The cause of the practical immunity of natives remains as yet to be discovered.

24. *Plague* caused fewer admissions and deaths during the year under review than during the previous year. In 1897 there were in the Native army 131 attacks with 82 deaths, whilst in the year under report there were only 94 attacks with 58 deaths. "Again, the chief point brought out is the benefit derived from quitting the infected lines and living in the open." Several medical officers express their belief in the protective effect of Haffkine's anti-plague serum. One of them writes: "From the facts given above regarding the mortality in relation to inoculation, there appears to be no doubt that the chances of recovery are much better in persons inoculated with Haffkine's prophylactic serum, and that such persons are less liable to be attacked."

25. *Respiratory diseases* are the chief cause of death in the Native army, and in 1898 no less than 38 per cent. of all the deaths were due to them. By far the most fatal of these diseases was pneumonia, which accounted for a ratio of 3·77 out of a total ratio of 4·13 deaths from respiratory diseases of all kinds. The admission-rate was highest, as usual, in the Indus Valley, and the death-rate was highest there also. The disease was most prevalent in the cold months of the year. The Medical Officer of the 19th Panjab Infantry thinks there is no doubt that the majority of cases of pneumonia are due to carelessness in the matter of clothing. "Even when sufficient warm clothing is supplied to the Native soldier, he constantly exposes himself needlessly, in spite of orders to the contrary." The greater liability of the Native soldier to pneumonia, as compared with his European *confrère*, is seen from a comparison of the records of admissions and deaths in the two armies. In the European army of India the ratio of admissions from pneumonia was 3·3 and of deaths ·61; in the Native army the ratio of admissions was 16 and of deaths 3·77 per 1,000 of strength.

26. From *dysentery* the admission-rate was much, and the death-rate considerably, less than in the preceding year. Whilst in the European army the admission-rate recorded from this disease was 29·8 and the death-rate ·78, in the Native army the former was 44·0 and the latter ·49. The cases were thus more numerous among the Native troops, but more severe among the European. The admission-ratios were much higher among Native troops in the hills than among European troops in the hills.

27. The prevalence of *venereal disease* in the Native army remains fairly constant from year to year. During 1898 the ratio of admissions was 40·0 per 1,000 of strength, as compared with 40·8 during the previous year. There were 8 deaths and 99 invalidings *directly* due to venereal disease. As usual, the Gurkhas suffered proportionately more than the other Native troops.

28. Under the influence of a return of more prosperous times, the *jail* population, which had increased to an average in the previous year of 118,107, fell during the year under report to 111,344. In the provinces which suffered most from famine in 1897, this decrease of itself, by reducing overcrowding in some of the jails, no doubt exercised a beneficial influence on the health of the prisoners. Moreover, the free population, having recovered from the debilitating effects of the previous famine, the health of the prisoners drawn from this population was doubtless better at the time of their reception into jail than the health of those received in the previous famine year. The sickness and mortality from almost all the diseases show a marked decrease. The prisoners shared in the immunity from *cholera*, which was so marked a feature of 1898 throughout India. The mortality from that disease decreased from a ratio of 3·94 in the previous year to a ratio of ·13 in the year under report. The decrease of mortality from *remittent fever* was slight; but the ratio of deaths from *dysentery* was only 5·72, as compared with a ratio of 11·07 in 1897. The death-rate from *diarrhœa* at the same time fell from 3·17 to 1·48. *Respiratory diseases* were only slightly less fatal; and *phthisis pulmonalis* was somewhat more fatal than in the previous year. *Dysentery*, usually the most fatal of jail diseases, caused 22 per cent. of the total deaths, *pneumonia* 15 per cent., and *tubercle of the lungs* 13 per cent., or, between them, half the total mortality for the year. As the Sanitary Commissioner with the Government of India remarks:—"There would be little exaggeration in saying that the prevention of bowel-complaints is the beginning and end of jail hygiene; as it certainly is the most difficult of the problems the jail medical officer has to face." Undoubtedly, malaria is one of the most important of the predisposing causes of dysentery, but unsuitable or ill-cooked food, as the Sanitary Commissioner observes, "is not only a predisposing but an exciting one." The Inspector-General of Prisons, North-Western Provinces, maintains that jail dysentery is infectious, and does not think that enough attention has been paid to the isolation of prisoners suffering from the disease. The same officer says pneumonia is always a fatal disease in jails, and, next to dysentery, gives most anxiety to medical

officers of jails. He thinks the prevalence of pneumonia and other respiratory diseases, and the high death-rates from these affections, have of recent years been a great deal due to the influenza epidemics which now occur almost yearly in the jails. Of *enteric fever* only 20 admissions with 9 deaths in a strength of over 111,000 were recorded during the year among the prisoners. None of the reports, it is stated, throw any light upon the origin of the cases. Of the 30 cases of *plague* which occurred in jails during the year, 29 took place in jails of the Bombay administration, and of these 30 cases 16 proved fatal. It is added that there were, besides, 10 cases with 4 deaths in the subordinate jails of Bombay.

29. The section of the report on the jails of India concludes with an interesting comparison of the mortality of prisoners with that of soldiers during the year. Taking the death-rate of European troops as 1, the death-rate of Native troops will be represented by ·6, and the death-rate of prisoners by 1·3. As already noted, bowel complaints, respiratory diseases, and tubercle of the lungs are the predominant causes of mortality in jails. The first of these, although malaria may act as a predisposing cause, are much influenced by the quality of food and water provided for the prisoners; whilst the last two are affected by the efficiency or deficiency of the ventilation of the prisoners' quarters, by the suitable or unsuitable description of clothing supplied to them, and by the nature of their occupation whilst undergoing their terms of imprisonment. The Inspector-General of Jails, North-Western Provinces, asserts that "the causes of the prevalence of tubercle are undoubtedly the sedentary occupations which have to be followed by a large proportion of the prisoners, and the inhalation of irritating particles of wool, cotton, &c., which must exist in the air of all factories." The mortality from bowel complaints recorded in the armies of India, as compared with that recorded in jails, may be represented by taking the mortality of Native troops as 1, when that of the European troops will be represented by 1·2, and that of the prisoners by 10·4. Similarly, by taking the liability to die of respiratory diseases among European troops as 1, that among Native troops is 5·4, and that among prisoners 6·4. The Sanitary Commissioner sums up the comparison in the following sentence :— "The chief cause of deaths among European troops was fevers, among Native troops respiratory diseases, and among prisoners bowel complaints."

30. The remaining sections of the Report, including those on the vital statistics, and chief diseases of the general population, vaccination and sanitary works, have already been dealt with in our *memoranda* on the provincial reports, and need not, therefore, be further noticed here. Last year we took occasion to remark on the tendency of the Annual Report of the Sanitary Commissioner with the Government of India to recover the enormous dimensions to which it had attained prior to the year 1895. Last year the Report with its Appendices covered 492 pages, as compared with 374 pages in 1895. The Report for the year under review has still further increased to 505 pages, and is again within 23 pages of being as large as it was in the year prior to its reduction in 1895. But it must be confessed that it would not be easy to select for curtailment any part of a report so ably and carefully prepared from beginning to end.

31. *Summary.*—The year 1898 was quiet, settled, and dry ; the monsoon set in somewhat late, but quickly extended over the country and gave rain in excess of the normal, or only slightly below it, to the greater part of India. The health of the European and Native armies of India was better than in the preceding year ; and the return of more prosperous times, in succession to a period of widespread scarcity, had restored the health of the general population. The sickness and mortality in the European army were less than in 1897 ; but the proportion of men invalided increased. The records of sickness, mortality, and invaliding for the year under review compare unfavourably, however, with the averages for the decennium 1886–95. As usual, ague and venereal disease were the chief causes of admission to hospital ; whilst enteric fever was, of all the diseases, by far the most destructive of life. The two diseases which were the chief causes of admissions were also the chief causes of invaliding. Of the four army commands, Madras was again the healthiest, as judged by its ratios of admissions and deaths ; whilst, judged in the same way, the Punjab command was the most unhealthy. The stations with garrisons of upwards of 1,000 which recorded the highest death rates were Peshawar and Quetta ; and those which recorded the lowest death-rate Poona, Bangalore, and Secunderabad. There was a recrudescence of influenza, and this seems to have been accompanied by increase in the admission and death rates from respiratory diseases. The European army shared in the immunity from cholera, which characterised the year generally throughout the Indian Empire. Enteric fever continued its destructive progress. The account given in the Report of the theories and opinions entertained by those who have made the disease the special subject of study and research, leads to the conclusion that many of most important problems connected with the origin and spread of the disease are still unsolved. The "solely water-borne" theory of the causation of enteric fever is being relinquished by many ; and the belief is gaining ground that the sources of infection are more varied and numerous than had hitherto generally been admitted. Of plague there were nine cases recorded in the European army, with two deaths ; six of the nine men attacked had been employed on plague duty. Tubercle of the lungs and pneumonia caused, between them, 75 deaths. Abscess of the liver was responsible for 102 deaths, and was 25 times more fatal among European than among Native soldiers. Bowel complaints were less prevalent and fatal than in 1897. There was a decided decrease in the ratio of admissions from venereal disease ; but this reduction in the admission-rate was not entirely due to less prevalence of the disease, many of the sick having been treated as out-patients at some stations. The Native, like the European, army was healthier than in the preceding year. As usual, the admission, constantly sick, and death-rates were much below those amongst the European troops. Ague was the chief cause of admissions, and pneumonia the most fatal of the diseases. As in the case of the European army, cholera, except in Assam and parts of Madras, was much less prevalent than usual in the Native army. Venereal disease varies little from year to year in the Native army ; in the year under review the admission-rate was 40·0 per 1,000 of strength, as compared with 362·9 in the European army ; and whilst enteric fever caused more than half the total number of deaths among European troops, it was credited with a total of only 17 deaths in the Native army. Respiratory diseases were the chief cause of deaths among the

Native troops, and accounted for 38 per cent. of the total deaths from all causes. Under the influence of the return of more prosperous times the jail population decreased, and the health of the prisoners improved. As in the European and Native armies, cholera was less fatal among the prisoners during 1898. Dysentery, pneumonia, and tubercle of the lungs together accounted for half the number of deaths from all causes in the jails. Briefly, "the chief cause of deaths among European troops was fever, among Native troops respiratory diseases, and among prisoners bowel complaints."

30*th June*, 1900.

No. 2.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Bengal for 1898.

The report commences with a useful account of the chief meteorological features of the year. The rainfall for the Province as a whole was in excess both of that of the preceding year and of the normal mean. The September and October rainfall, on which the failure or success of the winter rice crop so largely depends, was generally copious. The high mean temperature which prevailed in 1897 continued up to May of the year under review, except during the months of January and March. "With the setting-in of the rains this condition disappeared." In paragraph 24 is given a list of the prices of food grains for comparison with the prices for the previous year and with the average. From this table it is seen that the high prices of 1897 fell in the year under report to, or below, the average. "Reading these figures with the birth and death statistics," writes the Sanitary Commissioner, "it will be observed that the high prices ruling during 1897 greatly devitalized the people and thereby lessened their fecundity, as evidenced in the reduced birth-rate of many districts during 1898, whilst the distinct fall in prices during the year under review, due chiefly to plentiful agricultural outturn of the previous season, materially contributed to the general healthiness of the year, the people, who were well fed and well nourished, being better able to resist disease."

2. The *birth* and *death rates* are calculated on a population of 71,069,617. Enormous as this number is, it does not include the population of the entire Province. Vital statistics are not yet registered in the Chittagong Hill Tracts nor in the district of Angul. The births registered during the year somewhat exceeded two and a half millions, giving a ratio of 35·79 per thousand of population. This shows some falling-off as compared with the ratio for the previous year, when it was 36·94. The Lieutenant-Governor is not altogether disposed to agree with Major Dyson's opinion that the reduced birth-rate was chiefly due to the effect of the late famine, and, whilst admitting that the famine did without doubt exercise a certain influence in this respect, thinks the view of the Sanitary Commissioner must be accepted with modifications. It is pointed out in the Government review of the report that the North-Western Provinces and the Central Provinces suffered from famine and high prices simultaneously with Bengal, but that, unlike Bengal, both show, not a decrease, but an increase in their birth-rates. If, however, an examination is made of the birth-rates in the North-Western Provinces month by month, it will be seen that, as in Bengal, the first six months of the year show a decreased birth-rate as compared with the rate for the corresponding six months of the previous year, but that this is more than compensated for by the great increase in the last five months over the numbers in the corresponding months of 1897. In fact, the record of births during the year is similar in Bengal and the North-Western Provinces. In both Provinces, simultaneously subjected over wide extents of their areas to famine and high prices in 1897, the birth-rates were unusually low during the first seven months and unusually high during the last five months of 1898; the difference between Bengal and the North-Western Provinces being that, in the latter, the increase was so much more decided during the last five months that it not only made up for the deficit during the previous months but left the year with a surplus as compared with its predecessor. The birth-rate of 35·79 recorded in Bengal for the year is exceeded only by the rates recorded in the Punjab and North-Western Provinces. Although this is still a considerable way behind the estimated rate of 50 *per mille* of population for the Province, it shows that registration has made rapid progress since 1892, prior to which the records of vital statistics were so defective as to be perhaps as likely to mislead the sanitary inquirer as to guide him to safe conclusions.

3. The *death-rate* fell from 32·94, recorded in the previous year, to 26·57 per thousand of population, and was 2·20 below the rate recorded for the ten-year period 1888–97. The decrease was due to less prevalence of all the chief diseases, but more especially of fever and cholera. As usual, cholera and bowel complaints were more fatal in towns than in rural areas. This is due in the main, the Sanitary Commissioner thinks, to overcrowding in towns, with its attendant evils. Possibly, as we have elsewhere remarked, the differentiation of the causes of death is somewhat more intelligently effected in towns than in rural areas, and many deaths recorded in the latter under the head of "fever," more correctly classed as due to other diseases, such as dysentery and pneumonia. The mortality returns for Calcutta seem to lend support to this suggestion. It is stated that, "with the exception of fever, the mortality from the other death-causes was higher in Calcutta than in mofassil towns." In Calcutta there is a large number of medical practitioners, Native and European, who cannot fail to diffuse amongst the people in whose midst they practice some considerable knowledge of the diseases they are called upon to treat. This knowledge would tend to diminish the number of deaths referred to fever, and proportionately to increase the number credited to other diseases. The experiment carried out in the North-Western Provinces of obtaining from medical practitioners lists of deaths from diseases which they have been able to verify, shows very clearly that, if all deaths could be

referred to their exact causes, the number now credited to fever would show a marked decrease, whilst the numbers credited to other diseases would show a corresponding increase. The lesser fatality from fever recorded in Calcutta than in mofassil towns may thus, in part at least, be due to more accurate diagnosis. In the same way, the reference of deaths to fever may be somewhat less indiscriminate in mofassil towns than in rural areas. The question of the improvement of the record of the causes of death is a difficult one. Improvement will doubtless be slow of accomplishment; but the progress which registration of vital statistics has made in the Province of Bengal within the last six years encourages the hope that something may also be done to secure a more reliable record of the causes of mortality.

4. *Chief Diseases.*—The Province enjoyed unusual immunity from *cholera*. The deaths from this cause numbered 65,020 as compared with 196,247 in the preceding year. It was, however, present during the year in every district except one, and attacked 11,307 villages. If, therefore, the disease spreads by infection, as many believe, there were sufficiently numerous foci from which infection might be diffused. The special cause, or causes, of the unusual abeyance in which the disease remained during the year are still mostly matter of speculation. The Sanitary Commissioner gives his opinion in the following words :—"This happy result was chiefly due, I think, to the almost normal rainfall of the year and the satisfactory agricultural outturn almost everywhere, the people not being under the necessity of having to resort to polluted sources of water-supply and to unsuitable and unwholesome food which are the principal predisposing causes of cholera." The conditions stated are of a somewhat comprehensive character and such as would tend to lessen the predisposition to most diseases. With regard to the influence which the rainfall of the year may have exercised on cholera mortality, it is pointed out in the Government review of the report that in 1894, when the rainfall was almost the same as in the year under report, the mortality from both cholera and fever was the highest in the quinquennium. The Sanitary Commissioner seems to be on more secure ground when endeavouring to account for the comparative freedom from cholera of Puri, a place of pilgrimage, which always returns a high death-rate from this disease. "The immunity," he writes, "enjoyed by Puri in this respect was probably due to the improved sanitary condition of the place and to the opening of the East Coast Railway, which facilitated the rapid dispersion of pilgrims who congregate in Puri on the occasion of religious festivals several times a year." That crowds assembled under insanitary conditions are favourable to cholera outbreaks has been placed beyond dispute by the results of prolonged observation. It is no more, therefore, than might be expected that the dispersion of such crowds and the improvement of their sanitary environment would be unfavourable to its prevalence. The attempts to prevent cholera by the disinfection of wells by permanganate of potash are said to have had satisfactory results in the districts in which they were made. During the year, anti-cholera inoculation was performed on 4,296 emigrants to Assam; but no information regarding results was received up to the time the Sanitary Commissioner's report was written.

5. *Small-pox* was not unusually fatal. The 14,269 deaths recorded as due to it give a death-rate of only 0·20 per thousand of population. In Bengal, as in the other provinces in which measures had to be adopted with the object of preventing the spread of plague, vaccination suffered as a consequence of the need for employing officers of the Vaccination Department in superintending the carrying out of those measures. The plague inoculation scare and the introduction of the six-puncture system of vaccination are given by the Sanitary Commissioner as the causes to which the decrease in the number of vaccinations was chiefly due. The number of operations fell from 2,319,536 in the previous year to 2,147,452 in the year under report. "The extra two points of vaccination," writes Major Dyson, "were looked upon by the ignorant masses of the people as in some way connected with plague inoculation, and this retarded the progress of vaccination and accounts for the smaller number of operations performed during the past year." This is only another example of the difficulties which may have to be counted with when initiating harmless or even beneficial innovations amongst people so ignorant and conservative as the natives of India. The high percentage of successful cases, 97·99, is considered by Major Dyson to be due to the dishonest practice followed by vaccinators of including in the returns partial and even absolute failures as successful cases. Vaccinators in certain other provinces accomplish the same result in a somewhat different way: they omit their unsuccessful cases from their returns. In this way they show a high percentage of success without incurring the risk of detection which would attend the entry of unsuccessful cases as successful. Next to the absence of small-pox mortality, perhaps the proportion of infants vaccinated affords the best test of the efficiency of vaccination in a district. Judged by this latter test, the districts of Bengal show wide differences. Whilst in Malda the number of infants successfully vaccinated, per thousand, was as high as 856, in Puri it was only 24. Major Dyson does not see any reason why "with persevering care and tact on the part of the local officers, the ratio of successful infant vaccination cannot be much higher than at present." A satisfactory feature in the year's history of vaccination is the increasing use of vaccine lymph direct from the calf. The total number of vaccinations performed with this description of lymph increased from 175,001 in the preceding year, 1897–98, to 206,083 in the year under report. Commenting on a method of inspection of vaccination followed by some Civil Surgeons, in accordance with which the vaccinated children of several villages are assembled at one spot, the Lieutenant-Governor justly regards this as a most objectionable practice; "for it enables subordinates to set the seal of superior authority upon any concealment of deficiencies which a genuine inspection would have disclosed." The thorough inspection, case by case, of a single village would prove a more effectual deterrent against fraud than the inspection of a score of villages in the manner described. Indeed, slip-shod inspection is worse than no inspection; it gives confidence to dishonest vaccinators in the perpetration of fraud by showing them how easily such fraud may be concealed.

6. *Fever*, as in other years, was by far the most fatal of all the diseases. But the number of deaths assigned to it was less than in the previous year, and less than the average for the ten-year period 1888–97, "this being evidently due to the general healthiness of the year and to the plentiful outturn of crops almost everywhere." Accompanying this decrease in the prevalence of fever there was a falling-off in the quinine sales in the Province as a whole; but of the eight districts in which fever

mortality was higher than in the previous year, five show a corresponding increase in the sales of quinine. These facts seem to show that the demand for quinine arises from the belief the people have in its efficacy as a remedy for fever, and that its sale is not merely the result of official stimulus.

7. Doubtless from the same causes to which lessened fever prevalence was due, the mortality from *dysentery* and *diarrhœa* showed a decrease. The result of the examination of the returns furnished by medical practitioners who have recorded the causes of death in the cases treated by them, is to show that the mortality from bowel complaints is much understated. A more correct differentiation of the causes of death would increase the numbers attributed to dysentery and diarrhœa and correspondingly diminish the numbers credited to fever. Probably the greater mortality from bowel complaints recorded in towns as compared with rural areas is due, in part at least, to the more accurate diagnosis of disease in the former.

8. The expenditure on urban sanitation, excluding the construction and maintenance of roads, amounted to close upon twenty lakhs of rupees. The increase of expenditure on conservancy was largely due to "sanitary apprehension of the advent of plague." The four observation camps maintained with the object of preventing the introduction and spread of plague in the Province, alone cost nearly two and a quarter lakhs of rupees. At these camps 982,027 persons were examined and 39,023 detained. Yet, at only one of the four camps was there a single death from plague reported. At the Chausa camp there were five deaths from plague; at the other three, not one. Whether the results attained sufficiently compensated for so large an expenditure of money, and especially for so great an amount of unavoidable trouble and inconvenience to travellers, leaving out of count the indirect loss consequent on the interference with traffic, is a question which different persons might answer differently. Unfortunately, the exclusion of plague from the Province cannot be said to have been completely accomplished, although the measures adopted may have delayed the introduction of the disease.

9. *Summary.*—The year was characterised by generally normal meteorological conditions. The rainfall was seasonable, the harvest plentiful, and the prices of food grains lower than in the previous year. The influence of these conditions on the public health was shown in a marked decrease of mortality and, in the latter month of the year, in an increase of the birth-rate. There was lessened mortality from all the chief diseases. The number of deaths attributed to cholera was only about a third of the number recorded during the previous year, a result due, the Sanitary Commissioner thinks, to an almost normal rainfall and the satisfactory agriculture outturn almost everywhere. The mortality from small-pox was not high, reaching only to a ratio of 0·20 per 1,000 of population. Vaccination in Bengal, as in other provinces, suffered from withdrawal of some of the officers of the Vaccination Department to assist in carrying out the measures for plague prevention. The introduction of the method of making six punctures for lymph insertion had also the effect of creating suspicion in the minds of parents and rendering them averse from the submission of their children to the vaccinators. There was a considerable decrease in the total numbers vaccinated: these fall from 2,319,536 in the previous year to 2,147,452 in the year under report. Fevers and bowel complaints were less prevalent than in the previous year. The expenditure on urban sanitation, exclusive of the construction and maintenance of roads, fell little short of twenty lakhs of rupees. The establishment of observation camps with the object of preventing the introduction and spread of plague cost about two and a quarter lakhs of rupees. Apprehensions of plague invasion gave a wholesome stimulus to conservancy during the year.

No. 3.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of the North-Western Provinces and Oudh for 1898.

In marked contrast with its predecessor, the year 1898 was one of general prosperity and healthiness. The destructive effects of famine and disease were speedily obliterated, and the high death-rate of 1897 was followed in 1898 by the lowest on record, if that of 1893 be excepted. As the Secretary to Government puts it, the history of the year "primarily bears witness to the remarkable powers of recuperation shown by the people, and a rapid return to normal conditions, aided, it should be said, by an exceptionally healthy year and an unusual absence of epidemic disease." The principal meteorological features of the year did not deviate greatly from normal. At the majority of the stations at which complete meteorological records are kept, both the maximum and minimum temperatures were somewhat higher than the average. The rainfall during the first two and the last two months of the year was everywhere greater than during the corresponding months of the previous year. During the three comparatively dry months, March to May, the rainfall for the two years did not differ greatly; whilst during the monsoon period, June to October, the average fall was everywhere largely in excess of the average in the previous year, except in the western and submontane parts of the Province. In the latter, especially, there was a remarkable decrease from 92·44 to 47·45 inches. The table appended to paragraph 82 of the Report compares the prices of food grains for the 38 years commencing with 1861. Excluding wheat, the use of which is mostly limited to the well-to-do classes and cannot be regarded as one of the staple food grains of the bulk of the people, the mean price of these inferior grains was 18·19 seers per rupee as compared with 12·75 for 1896 and 10·25 for 1897. "These prices," writes the Sanitary Commissioner, "witness a return to prosperity." A study of the table of prices including the period from 1861 to the year under review

is suggestive. Whilst for the first 26 years of this period, the mean quanity of food grains which could be bought for a rupee was, during two of the years, over 30 seers, and during all of the other years, except seven, more than 20 seers; the quantity in the last 12 years of the period obtainable for a rupee only slightly exceeded 20 seers during two of those years, and for the remaining 10 years was always less, and often greatly less, than 20 seers. In other words, food is shown to be getting dearer. If the data were available, it would be useful if, in future tables of prices of food grains, an estimate were given of the movement of wages accompanying the movement of prices of food.

2. The birth-rate recorded for the year under review, calculated on the census figures of 1891, rose from 31·10 in the previous year to 37·35 in the year under review. The number of births exceeded the number of deaths by no fewer than 467,406, "giving a rate of excess of 9·97 *per mille*." It is interesting to notice that during the first seven months of the year, the birth-rate was below the rate for the corresponding period of the preceding year, a result due, no doubt, as the Sanitary Commissioner observes, to the enfeebled condition of the people during the seven months preceding November, 1897. The last five months of the year, however, show a high birth-rate as compared with the corresponding months of the previous year, indicating the return to health of the people when the famine conditions had passed away.

3. Whilst, as stated, the birth-rate showed a marked rise during 1898, the death-rate, on the other hand, fell from 44·46 per 1,000 of the population to 27·38. There were 613,273 fewer deaths recorded than in 1897. The death-rate was lower than the quinquennial mean by 6·52 *per mille*. Some of the districts with the lowest death-rates were those which had suffered severely from famine, and the Sanitary Commissioner considers it satisfactory to see these districts in the list. During a severe famine many of the diseased and feeble disappear, leaving a population composed of the most healthy and robust. In such a population the mortality may be expected to be unusually low. There is, perhaps, no more sensitive index of increased or decreased healthiness in a community than the rise or fall of the death-rate amongst infants. In 1897 this rate was 272·5; in the year under review it was only 224·0.

4. The result of the endeavour to differentiate the causes of death by a professional agency tends to confirm the conclusion that the number of deaths recorded under the heading of "fever" by chaukidars and other unprofessional agents is excessive; whilst the number under other headings, such as diarrhœa and dysentery, pneumonia and lung diseases, &c., are correspondingly under-stated. Although this conclusion is established beyond any question, it is not very clear how improvement in the differentiation of disease is practicable unless at prohibitory expense. One of the results of the verification of deaths by professional agencies is worthy of special attention. It is frequently suggested as an explanation why deaths from enteric fever amongst natives are so rarely recorded, that the disease is largely prevalent amongst native children, and that having generally had an attack in infancy, native adults enjoy comparative immunity from the disease. This hypothesis seems hardly to be borne out by the records tabulated by professional agencies. "In all, 9,254 cases were verified, of which 4,103 were children under 16 years of age." Of these 9,254 deaths, two only were from enteric fever; and apparently, judging from the statement made in paragraph 25, neither of these occurred amongst the 4,103 children under 16 years of age. The theory, therefore, that widespread prevalence of enteric fever amongst native children may be assumed to account for the rarity of that disease amongst adults receives no support from the record of the causes of death furnished by professional agencies.

5. There was a remarkable immunity from epidemic disease during the year. Of *cholera* deaths only 2,508, or equal to a ratio of 0·5 per 1,000 of population, were recorded. During the months of the year when cholera is generally most prevalent, the number of deaths from it was insignificant. The months of greatest mortality were October and November, the latter being credited for the first time during the entire period included between 1877 and 1898, with the highest rate for any month of the year. It might have been useful to endeavour to account for the unusual abeyance in which the disease remained during the year. An investigation of the conditions determining or influencing its absence during particular seasons, might lead to results hardly less valuable than those to be obtained by inquiries into those determining its prevalence. Cholera deaths were reported in the Province every month of the year, but out of a total number of 107,132 villages, in only 516 were deaths due to it recorded. The cause of this comparative quiesence of the disease and its apparent inability to spread during 1898 remain as much a mystery as, during other years, does the cause of its rapid development and dispersion.

6. As in the case of cholera, so also in that of *small-pox*, there was a remarkable immunity from epidemic prevalence. Only in one of the past 28 years have fewer deaths from small-pox been recorded. In 1897 the small-pox deaths numbered 87,127. In the year under report the number was only 2,419. The great prevalence of small-pox in the preceding year explains to some extent the comparatively small mortality caused by it in the year under report. According to Farr, of every 1,000 persons attacked by small-pox from 150 to 300 die, or from 15 to 30 per cent. of the cases terminate fatally. Taking 20, a percentage intermediate between the two extremes given by Farr, as representing the deaths to attacks in India, it would follow that the total number of deaths from small-pox in 1897 would represent 435,635 attacked by the disease. All of those attacked but who survived would be protected against future attacks; consequently, by no means an insignificant portion of the unprotected must have been rendered proof against further attack by the epidemic of the preceding year, and so have substantially lessened the number of those susceptible of attack in the year under report. The Annual Report on Vaccination for the year 1898–99 shows that the ground lost during the preceding year had not yet been entirely recovered. During 1897–98, the total number of successful primary vaccinations fell, under stress of famine conditions, from 1,308,941 to 1,182,395. With the return of prosperity and the release of the members of the vaccination staff from the extraneous duties imposed upon them in connection with plague, the numbers successfully vaccinated again rose to 1,227,261, showing an increase over the preceding year of 44,708, but failing to reach the total of 1896–97 by no fewer than 81,680. The quality of the work, however, which had

fallen off in the famine year at the same time that the quantity had decreased, was not only restored, but was in advance of that recorded in 1896–97. During the latter year the percentage of successful cases in primary vaccination, where the result was known, was 94·65: in the following or famine year it fell to 93·74, but rose in the year under review to 94·96. The number of successful re-vaccinations remained practically the same in 1898-99 as in the preceding or famine year, and fell short of the number for 1896–97 by 10,487. One of the most promising features of the year's work is the increase in the number of infants successfully vaccinated. Whilst in 1896–97 these numbered 578,055 and in the following year 551,113, they increased during the year under review to 637,129. Obviously, however, when even the latter number is compared with the 1,751,725 births recorded in the calendar year 1898, prolonged and sustained effort will be required before anything approaching to the complete protection of the infant population of the Province can be attained. After deducting the 359,621 deaths of children under one year of age, there would remain available for vaccination 1,392,104, as compared with the 637,129 successfully vaccinated. The Government of these Provinces, no doubt for sufficient reasons, still trusts mainly to the use of humanised vaccine lymph. "Meantime, the arrangements hitherto existing have continued, under which vaccination operations are carried on in the hills in the hot weather and rains, and human lymph thus obtained is despatched to the plains in September and October. There are bovine lymph depôts at Allahabad and Lucknow, but, owing to the difficulty of preservation, the extent of these operations is local." This acquiescence in the continued use of human lymph finds little favour elsewhere. In the review of vaccination for 1894–95, the Secretary to the Madras Government writes:—"Every effort should be made to discontinue the use of human lymph; that this should still have been employed in such districts as Ganjam, Godavari, and Vizagapatam, where there are hill tracts remote from centres from which lymph can be obtained, is capable of explanation; but this is not the case with Nellore, where, if proper arrangements were made, there should have been no need to use lymph obtained from the human subject." Calf lymph, unless used direct from the calf to arm, gives a low percentage of success. "Calf lymph in tubes," writes the Officiating Sanitary Commissioner of the North-Western Provinces, "unmixed with any preservative has not good keeping qualities in this climate." He adds:—"Very thorough supervision, and a training in antiseptic methods far in advance of that given to vaccinators, are required in the preparation of lymph preserved by admixture." This would seem to be borne out by results. The following is the experience recorded in the Madras Presidency for the year 1898–99:—"As usual fresh animal lymph shows the greatest percentage of success, viz., 97·6; then comes vaccine sent out between glass plates without any preservative, then lanoline paste, and lastly glycerine, with 95·9, 88·0, and 82·4 respectively." Seeing that, with the experience gained in the preparation of this mixture, a percentage of only 82·4 of success follows its use, further endeavour would still seem to be needful before it can come anywhere near to the level of success claimed for bovine or humanised lymph "without any preservative."

7. "In the year under review," writes the Secretary to Government, "the monthly mortality took a thoroughly normal course, which is, in every year, regulated in the main by the vast preponderance of the deaths under the head of fever in these Provinces." The deaths from *fever* during the year were fewer by 400,120 than in the preceding year, a decrease of 27·3 per cent. So with *diarrhœa* and *dysentery;* the deaths recorded as due to these fell from 58,822 in the previous year to 23,574, or less than half. The latter figures indicate that to hard times and an insufficient or unwholesome dietary, a season of comparative comfort and abundance had succeeded.

8. An outbreak of plague occurred in the town of Jwalapur, near Hardwar. The first case took place on the 9th of January, and the disease did not finally disappear before the 28th of May. The measures of evacuation, segregation, and disinfection which were energetically put in force, appear to have had the effect of preventing the spread of the disease beyond the town first attacked and the neighbouring villages.

9. The chief sanitary defects in the municipalities of the Province, as well as the remedial measures adopted for their removal, are succinctly described in Annual Form XI. The report of the Sanitary Engineer is largely taken up with an account of the working of the municipal waterworks in the Province. The Sanitary Board, which met three times during the year, have recorded their satisfaction with the quality of the water delivered by the several waterworks, but have recommended that samples should be sent monthly from each of the municipal waterworks for qualitative examination by the Government Bacteriologist.

10. *Summary.*—Unlike its predecessor, which was a year of famine and great mortality, the year under review was one of prosperity and exceptional healthiness. Whilst the death-rate fell from 40·46 in the previous year to 27·38, the birth-rate rose from 31·10 to 37·35. The absence of epidemics of disease was one of the marked features of 1898. The number of deaths from cholera was the lowest recorded since trustworthy registration began in 1871. Small-pox, which carried off 87,127 of the population during the previous year, was accountable for only 2,419 deaths. So, likewise, with regard to fever and bowel complaints; whilst the former was credited with 400,120 fewer deaths than in 1897, dysentery and diarrhœa caused less than half the number of deaths. The energetic and drastic measures adopted with the object of circumscribing and extinguishing an outbreak of plague near Hardwar were completely successful. By the end of May the disease had entirely disappeared. Water-supply and drainage schemes continued to occupy the attention of the Government. Although considering the water supplied by the municipal waterworks to have been satisfactory during the year, the Sanitary Board recommended that samples should be sent monthly by each municipality to be qualitatively examined by the Government Bacteriologist. This proposal has received the sanction of the Government. The great drainage works at Benares continued to make progress, and surveys of several important towns were being carried out or completed with a view to the introduction into them of an improved system of drainage.

25th May, 1900.

No. 4.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of the Punjab for 1898.

Excepting in two statements, given in the Appendix, recording the rainfall at the headquarters of the 31 districts of the Province and the prevailing rates of wheat, rice, and gram, no reference is made in the Report to the meteorology of the year. In view of the intimate connection which is acknowledged to exist between the weather and the state of the public health, it might not be out of place if in future reports the Sanitary Commissioner devoted a paragraph to a brief sketch of the chief meteorological features of the year. In the same paragraph might also be noted whether the ordinary food grains were plentiful and cheap, or the reverse; and whether the wages of the labouring classes showed a rise or fall. The sanitary history of a year can hardly be considered to be complete unless it gives some account of the influence which the weather, prices of food, and wages of the labouring classes seem to have exercised on the public health during that year. From the two statements already referred to it would appear that the total rainfall in 1898 was nearly the same as that in the previous year; in the former 24·14 inches of rain were recorded, and 23·62 in the latter. In both years the fall was considerably below the average of the previous 10 years, which was 27·77 inches. In every quarter of the year under report, wheat, rice, and gram were cheaper than during the corresponding quarters of the preceding year; whilst the mortality was greatly higher during the first two quarters of 1898, somewhat higher during the third, and greatly lower during the last quarter than in the corresponding quarters of 1897.

2. The *birth-rate* for the year, 41·0, shows some falling off as compared with that of the previous year, when it was 42·6 per 1,000 of population; but was again the highest recorded in any province in India. There is a wide divergence between the rates recorded for different districts. Three districts record birth-rates exceeding 53, and two districts birth-rates less than 30 per 1,000 of their population. In the latter two the conditions are exceptional. In the population of one of them, Simla, males largely preponderate; and in the other, Peshawar, the population consists chiefly of "Muhammadans of the Afghan type," who are averse to register their births and deaths, female births more particularly. In the chief towns of the Province also there is a wide divergence between those recording the highest and those recording the lowest birth-rates. Whilst Sialkot and Chunnian are credited with rates of 53 and 54 respectively, Kohat and Dera Ghazi Khan fail to reach to half of these rates, and record respectively 26 and 23 *per mille* of their populations. In the Government review of the Report the fluctuations between the birth-rates recorded in the year under report and those recorded in the previous year are noticed, and the comment added: "The fact that the calculations have to be made on the figures of the census of 1891 accounts for a great deal in these days, when great changes are going on in consequence of the construction of railways and canals." If the Sanitary Commissioner can succeed in securing an accurate record of children born dead, according to their sex, there is no doubt, as he observes in the concluding sentence of the fifth paragraph of his report, that in such a record might be found a clue to the detection of infanticide in those places where this crime is still practised.

3. The *death-rate* for the year was practically the same as in the previous year. As the birth-rate was the highest recorded in any Province of India, so likewise was the death-rate of 31·05 the highest in any Province, except Assam. A high birth-rate is usually accompanied by a high death-rate. A glance at the tables on pages 1 and 4 will show that the 10 districts with the highest birth-rates include 7 of the 10 districts with the highest death-rates. The district of Dera Ismail Khan is a notable exception; it records a birth-rate of 30·6, nearly the lowest in the Province, and yet has the highest death-rate, 40·11. "Although the district has a bad reputation for a virulent form of fever," writes the Lieutenant-Governor, "it seems possible that there may be something wrong about the figures." The death-rates varied greatly in the several districts, but within narrower limits than the birth-rates. Dera Ismail Khan records the highest death-rate, 40·11, and Montgomery, 21·27, the lowest. As measured by their record of mortality, the 45 principal towns, taken together, were healthier than during the previous two years; yet does their death-rate of 34 considerably exceed the provincial rate of 31·05. The greater healthiness of the rural as compared with the urban population is further shown by a comparison of the infant mortality in town and country. In the 45 principal towns of the Province the ratio of mortality amongst infants was 245 per 1,000 of children born; in the country the ratio was 226 per 1,000. The town of Dera Ismail Khan records the enormous death-rate amongst infants of 400. The chief sanitary defect noted in the case of this town is the unsatisfactory state of the drainage; the water supply is said to be good and sufficient.

4. *Registration of vital statistics* continues to receive much attention, and with results which are highly satisfactory. The Sanitary Commissioner shows that, although the death-rate amongst infants in England is far below the rate recorded in India, yet the *proportion* between the infant and general death-rates in England is very nearly the same as in India, "a point," he adds, "which goes to show how steadily the system of registration is improving in this Province."

5. *Chief Diseases.*—Although it is customary to give *cholera* a foremost place in the list of the chief diseases in the Provinces of India, it is only at long intervals that this disease is the cause of more than an insignificant mortality in the Punjab. During the year under review "the Province was practically free from cholera." With the exception of the 30 deaths in Umballa cantonment, there were only three deaths recorded in the entire Province. That the disease should have appeared in, and restricted its spread almost exclusively to, a military cantonment, with its elaborate system of sanitation carefully carried out under expert supervision, seems not a little remarkable.

6. The number of deaths due to *small-pox* fell from 45,084 in 1896 to 16,077 last year, and now, in the year under report, to 4,998, showing that the severe epidemic of 1896 is dying down. The Sanitary Commissioner points out that the small-pox chart shows at a glance the diminished prevalence of the disease during the period from 1879 to 1898, as compared with its prevalence during the preceding series of years from 1867 to 1879. This diminished prevalence since 1879 coincides, he adds, with the institution of the Vaccination Department as it is at present. Yet it cannot be overlooked that, even under the existing system of vaccination, violent epidemics are still possible. The deaths from small-pox in 1896 reached a rate of 2·19 per 1,000 of population, and was not exceeded in any year since 1869. Vaccination, owing to several causes, cannot be said to have made much progress during the year under review. In fact, if the total number of persons vaccinated in 1898–99 be compared with the total numbers for each of the two preceding years, it will be seen that there has been not only no increase, but a decrease. As compared with the previous year, the decrease amounted only to 4,623 cases ; but as compared with 1896–97, to no fewer than 61,545 cases. During each of these three years the strength of the Department remained practically the same. The cause of the falling-off in the numbers vaccinated is thus explained in the Government review of the report. "Doubtless the absence of the Deputy Sanitary Commissioner on plague duty, and the consequent want of supervision over the vaccinators, had much to do with this falling-off ; perhaps also the partial change of system to working in bodies, to be referred to presently, instead of in pairs, had something to do with it." A perusal of the record of their opinions regarding the system of setting the vaccinators to work in bodies rather than in pairs, with the object of securing their better supervision, shows that the Civil Surgeons are by no means unanimous regarding the superiority of the former system. The Lieutenant-Governor has, however, no objection to giving the system of working in bodies a further trial, but thinks that all of the Civil Surgeons do not understand precisely what the system is meant to be, and has instructed the Sanitary Commissioner to put more clearly before them what the system is, and how it is to be worked. In addition to the other causes mentioned as having had an unfavourable effect on the season's work, the failure of the animal lymph preserved in vaseline is noted. Regarding this, the Sanitary Commissioner writes :— "This is a matter in which we must expect a good deal of antagonism ; but having worked with it so successfully myself when I was Civil Surgeon in Rawal Pindi, I can only say that when proper arrangements are made, and our depôts properly fitted with the necessary appliances, and under good supervision, this all disappears." This may be true, but, with the agents at his disposal, it is at least doubtful if the conditions necessary to secure success can in practice be counted upon. Elsewhere in his report, the Sanitary Commissioner states that almost every vaccinator in the province *hates the system*. If the working of the system has of necessity to be entrusted to agents who hate it, success can hardly be looked for with confidence. In the neighbouring North-Western Provinces, the use of vaccine lymph preserved in glycerine has not been satisfactory. The reasons for this, which have been stated in the Vaccination Report for those Provinces, are worthy of attention. The use of calf lymph preserved in glycerine has been persevered with in the Madras Presidency for many years ; but with, as result, a comparatively low percentage of successful cases. The percentage of successful cases in primary vaccination in the Punjab was 95·50, as compared with 95·10 in the previous year, and with 93·97 in 1896–97. The percentage of success in secondary vaccination, on the other hand, fell from 59·21 in the previous year to 58·85 in the year under report. This falling-off probably merely indicates that more care is taken to see that vaccinators do not record every case showing some degree of local irritation at the point of lymph insertion as "successful."

7. Cases of *plague* continued to occur throughout the year, but they were confined to very limited areas in the districts of Hoshiarpur and Jullundur. The total number of deaths caused by the disease fell somewhat short of 2,000.

8. *Fever*, *dysentery*, and *diarrhœa* prevailed to much the same extent as in the previous year. The district of Dera Ismail Khan records the high death-rate of 32·26 from fever. The result of the revised scheme for placing quinine more within reach of the people in remote places will not be known, it is stated in the Government review of the report, until the end of the current year.

9. *Sanitary Works.*—The list of water-supply and drainage schemes, completed or in progress during the year, shows that many useful sanitary works of a permanent nature are steadily being carried through. The expenditure under the two heads of water-supply and drainage amounted to close upon two lakhs of rupees. In commenting on the statement prepared for the purpose of showing the influence on the health of towns and rural circles of the introduction into them of drainage or water-supply schemes, or both, the Sanitary Commissioner says :—"With very few exceptions, the statistics show a marked improvement in the health of the towns in which the water-supply was introduced. It is only after some years that the people take to using pipe water ; one great objection to pipe water is that it is so much warmer than well water." The improvement effected by the water-supply in Delhi, Umballa, Lahore, and Haripur has been very marked.

10. The experiment of endeavouring to excite an interest in sanitation in rural districts by granting rewards in the form of remissions of a considerable fraction of the revenue demand of the one village in each tahsil of the district which showed the best results in sanitary improvement is, we are glad to see, to be persevered with. Such a method of inducing the people to pay attention to their sanitary surroundings seems to be free from many of the dangers of the more drastic methods of enforcing sanitary improvements which find favour in some quarters. Time and patience are necessary elements in schemes having for their object to induce the people of India to relinquish their ancient habits and customs in favour of new ones. The Sanitary Board did not meet during the year. It possesses only consultative functions, and the general feeling amongst the members seems to be that without executive powers, meetings would be without useful result.

11. *Summary.*—The sanitary history of the year is fortunately undiversified by a record of famine or violent epidemics of disease. The birth-rate was the highest recorded in any province of India, and the death-rate was only exceeded in Assam. A high death-rate is the usual concomitant of a

high birth-rate. The recorded birth and death rates in the Punjab testify to the high degree of accuracy in the registration of vital statistics which has been reached in that Province. Of the chief diseases, cholera was practically absent, only 33 deaths having been attributed to it. Plague never succeeded in getting outside the narrow limits within which it was confined in portions of the two districts of Hoshiarpur and Jullundur. It was credited with just under 2,000 deaths. The violent small-pox epidemic of 1896, which had continued to decrease in fatality in the following year, further declined in the year under report, when it accounted for only 4,625 deaths. Vaccination cannot be said to have made much progress; the total number of persons vaccinated shows a slight decrease as compared with the total number for the previous year, and a more serious decrease as compared with the number for 1896–97. For this unfavourable result several causes are assigned, and amongst them the want of success in the use of the vaccine lymph preserved in glycerine. The Sanitary Commissioner describes the causes which contributed to the failure of the lymph thus preserved, and mentions the arrangements which, he believes, would secure its success. But as he states that the vaccinators are hostile to the use of vaccine lymph preserved in glycerine, the attainment of the success which he hopes to secure is probably some way off. Fevers and bowel complaints were not more fatal than ordinary. The endeavour to place quinine within easier reach of the people in remote parts of the Province is being persevered with. Steady progress is being made in the prosecution of sanitary improvements throughout the Province. The list of drainage and water-supply schemes is a long one. The effort to induce the rural population to bestow more attention on the sanitary improvement of their villages, by offering rewards in the shape of the remission of portions of the revenue demand, is being pressed upon the attention of the district authorities.

No. 5.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Burma for 1898.

The history of the year from a sanitary point of view was not very eventful. It is only by degrees that registration of vital statistics is being extended to those parts of the Province, the last brought under British rule. The districts included in Lower and Upper Burma now number 38, according to Statement No. 1 of the Vaccination Report, but in 18 only of these are births and deaths recorded. From the Government Resolution on the Sanitary Report we learn that "registration of births and deaths has been extended to three municipal towns in Upper Burma, making 12 towns in all in which full statistics are recorded." A commencement has also been made, from January of the year under review, with the registration of deaths, but not also of births, in selected districts of Upper Burma. Seeing that in parts even of Lower Burma arrangements for the record of vital statistics are still incomplete, it will probably be some years yet before a system of registration can be introduced into all the districts of Upper Burma, the most recently acquired portion of the Province. The part of the population of Burma already brought under registration is stated to be 4,510,697, a number which differs slightly from that given in the previous year, owing to the changes described by the Sanitary Commissioner in paragraphs 4 and 5 of his Report. On these figures the ratios of births and deaths throughout the Report are calculated.

2. The *birth-rate* for Lower Burma was 34·11 per thousand of its population, as compared with 31·82 for the previous year. Referring to the table given in paragraph 11 of the previous year's report, it will be seen that the birth-rate for the year under review is the highest yet recorded in Burma, the next highest having been 32·27 in 1896. This shows that registration, under the persistent attention bestowed upon it, is steadily improving in the Province. In the table just mentioned, the progress which the registration of births and deaths has made during the past 26 years may be clearly traced. In 1873 the recorded birth-rate, per thousand of population, was 18·45, or little more than half of that now reached. But it is certain that the increase in the birth-rate is not altogether due to better registration. "The country is being rapidly opened up and the population, both urban and rural, is increasing very fast through excess of births over deaths, and immigration." It must follow that, during the latter years, more especially of the ten-year inter-census period, the births, resulting as they do from a larger population, will be more numerous than in the preceding census year; whilst the smaller census population figures are still used as the basis on which the ratio of births is calculated. The births of a larger population calculated, not on the population which furnishes them, but on a smaller one, will, it is evident, have the effect of giving a ratio higher than it ought to be. If the increase of the population were due to excess of births over deaths alone, the population could be estimated by adding this excess to the population of each preceding year; but in Burma immigration seems to play a very important part in raising the strength of the population, and it is not known if a complete record of immigrants is kept.

3. The recorded *death-rate* of 26·13 was practically the same as that of the previous year. As with births so with deaths, there has been a remarkable improvement in their registration during the last 26 years. Likewise, and from the same cause—increase of population since last census—the ratio of deaths, calculated on the smaller census population, is higher than the ratio would be if calculated on the greater population of the year under review. Growth of population thus combines with improved registration of vital statistics to raise the recorded birth and death rates. As the Sanitary Commissioner points out, some of the apparent anomalies in the birth and death rates in the towns of the Province can be explained by the relative proportions of the sexes in

these towns. Rangoon, for example, records a birth-rate of only 18·77, as against a general urban birth-rate of 25·78 for the Province. It cannot be supposed that in the chief town of the Province and the seat of Government registration of vital statistics is more backward than in other towns. If additions to the population of Rangoon through immigration tended to raise the birth-rate, the rate would undoubtedly be a high one. The explanation of the abnormally low birth-rate is to be found in the circumstance that females constitute less than 31 per cent. of the population of Rangoon town. Contrary to the rule that a high birth-rate usually accompanies a high death-rate, "the lowest birth-rates and the highest death-rates are returned by towns." In Burma, the urban birth-rate was 27·78 *per mille* of population, and the death-rate 33·10; whilst the rural birth-rate was 35·34, and the rural death-rate 25·09. We have, thus, results the exact opposite of those that might have been expected. When, however, the constitution of the urban is compared with that of the rural population, one at least of the causes of these abnormal ratios is revealed. In the urban population of the Province, to every 100 females there were 155 males; and in the rural population to every 100 females 107 males. So far from the seemingly abnormal ratios of births and deaths in towns being due to more defective registration than in rural areas, the Sanitary Commissioner believes that urban is more accurate than rural registration. Certainly, a death-rate in rural Burma of 25·09 seems less likely to be an approximation to the actual ratio than 33·10 in urban Burma. As in the Indian Provinces, the mortality amongst infants is high and continues to rise. Of male children under one year of age 287·35 died *per mille*, and of female children 193·96, as compared with 269·24 of the former and 188·29 of the latter in the previous year. How far this increase in the infant death-rate from 228·93 of male children and 161·42 of female children in the preceding five-year period 1893–97 is due to greater infant mortality and how far to improved registration is uncertain.

4. *Chief Diseases.*—Burma was no exception to the rule that the year under report was one of low *cholera* mortality thoughout the Indian Empire generally. The number of cholera deaths recorded fell from a total of 8,538 in the previous year to 2,972 in the year under review, and was the lowest recorded since 1893. Commenting on the unsatisfactory results of the inquiries hitherto made regarding the origin of the outbreaks of cholera in jails, the Sanitary Commissioner advises that specialists should be promptly be made available for the purpose of thoroughly investigating on the spot epidemics of cholera occurring in jails. In our memorandum on the Sanitary Report of the Central Provinces for 1895, when dealing with the question of the importation of cholera into five of the jails in which the disease had appeared, we wrote :—"We have thus five groups of people under the constant observation of scientific experts, and yet cholera appears in each group without its having been possible to trace the cause of its appearance. We may well hesitate, therefore, to accept the confident assertions made regarding the importation of the disease into villages or into fairs, such assertions resting in most cases on statements obtained from ignorant villagers or village watchmen." Inquiries by specialists on the spot into the origin of the outbreaks of cholera in jails, as recommended by the Sanitary Commissioner, would seem likely to afford more useful results than those obtained regarding outbreaks in towns and villages in which the conditions needful for exact observation of all the facts can seldom be present. An inquiry into the cause, or causes, to which the comparative abeyance of cholera during 1898 was due, might prove as useful in increasing our knowledge of the disease as an inquiry into those which determine its prevalence in years of its epidemic prevalence.

5. One has to go back to 1884 before coming to a year which records so high a mortality from *small-pox* as the year under report. The deaths from this disease numbered 4,826, as compared with 1,950 in the previous year. Of the victims, 69 per cent. were infants or children under twelve. Vaccination continues to make satisfactory progress both as regards the numbers vaccinated and the percentage of successful cases. From a ratio of 27·73 per 1,000 of the population protected against small-pox in 1893–94, the ratio has reached in 1898–99 a ratio of 53·03. The increased amount of work recorded is in part due to the increase in the strength of the vaccination establishment; but, apart from this increase, the number of operations performed by each vaccinator has risen from an average of 2,526 in the previous year to an average of 2,635. At the same time, the percentage of success in revaccination cases fell from 61·38 to 59·55. This fall in the percentage of success is probably only an indication that the tests by which success in revaccination is determined have been somewhat more stringently applied. If such be the true explanation the decrease is not a matter for regret. Judged by the amount and quality of the work recorded, vaccination, as we have said, is making good progress; but judged by the practical test of the measure of protection against small-pox which it has conferred on the population, there is less room for satisfaction. The ratio of small-pox deaths, per thousand of population, in the calendar year 1898 was 1·07, as compared with 0·44, the mean ratio of the previous five years; and the number of small-pox deaths is the highest recorded since 1884. The extraordinary falling-off in the number of persons vaccinated in the town of Rangoon from a total of 16,083 successful primary operations in 1895–96 to 5,516 in 1898–99, is said by the Health Officer to be for the most part only apparent and not real, as the accuracy of the figures of 1896–97 and the previous years is, in his opinion, open to grave doubt. Accompanying this decrease, apparent or real, the small-pox deaths in the town reached a total of 132 during the year under review. Except in three municipal towns, of which Rangoon is one, in all the rest the number of children vaccinated exceeded the number estimated to be available for vaccination. This excess is explained to be due, in the first place, to large numbers of children having been brought from the adjoining villages into the town to be vaccinated, and to a practice which is, or was, common elsewhere in India, of municipal vaccinators, on their completing the vaccination of all persons available in the towns, extending their operations to the surrounding villages, and including the persons vaccinated in these latter in the returns for the municipal towns.

6. The number of deaths caused by *fevers* was the highest on record. This may not be altogether due to increased fever mortality, but may be partly the consequence of more complete registration and partly of growth of population. No doubt a large proportion of the deaths ascribed to fevers would have been recorded under other heads had the record been made by persons possessed of some medical knowledge. The Sanitary Commissioner thinks 50 per cent. of the deaths credited to fevers

were really due to other causes. The scheme for the distribution of quinine, so as to place it within reach of the people of remote tracts of the country, is still being persevered with, although the Lieutenant-Governor is disappointed to learn that it has progressed less than it might have done. The mortality from *dysentery and diarrhœa* was slightly less than in the preceding year and seems to call for no special remark.

7. Up to the end of the year, only one case of *plague*, and that an imported one, had appeared in the Province. Appended to the Sanitary Report, and covering nearly nine closely-printed pages, is an elaborate list of precautions to be used against the importation of plague and of rules for the prevention of its spread in towns and villages. The rules for dealing with the segregation of the sick, their removal to hospitals, and for the disinfection of houses in which cases of the disease have occurred, unless worked with much discretion, may not have the effect desired of restricting the diffusion of the disease. Experience shows that to avoid the inconvenience arising from the strict enforcement of these rules, the people are prone to conceal their sick, and even to abandon their homes, carrying with them in their flight the seeds of the disease to towns and villages hitherto free from infection.

8. *Sanitary Works.*—The list given in Annual Form No. X. of the Appendix to the Report of Sanitary Defects in the Municipalities of Burma, is a long one, and the Sanitary Engineer whose services have now been placed at the disposal of the Government will find ample employment for his energies for years to come in the task of removing them. There seems to be some prospect of a reorganisation of the superior medical staff of the Province being effected in the near future. It is not reasonable to expect that under the existing system, in accordance with which the same officer has charge of the Sanitary, Medical, Jail, and Vaccination Departments, sanitation could receive the amount of attention which its importance deserves in a great and rapidly developing province like Burma. "The Sanitary Board is reported to have done practically nothing" during the year under review.

9. *Summary.*—The sanitary history of the year was marked by no very unusual events. In a comparatively new province like Burma, a large portion of which has only recently come under British rule, it will probably take years of patient labour to bring its vital statistics into line with those of the older provinces. In Upper Burma, little more than a commencement has yet been made in the registration of vital statistics. Even in Lower Burma, the older part of the province, returns of births and deaths for the entire population are not yet available. The birth-rate for Lower Burma, during the year under report, was equal to a ratio of 34·11 per thousand of the population, and the highest hitherto recorded. This high rate indicates improvement in registration, and also, it is believed, increase in the numbers of the population since last census was taken, an increase due partly to excess of births over deaths, and partly to immigration. The recorded death-rate was 26·13, and was practically the same as that of the previous year. Some of the apparent anomalies in the birth and death rates the Sanitary Commissioner shows to be due to the peculiar constitution of the communities furnishing those rates. For example, in Rangoon town, which records a birth-rate of only 18·77 *per mille*, females constitute less than 31 per cent. of its population. Burma shared the comparative immunity from cholera during 1898 enjoyed by the Indian Empire generally. Not since 1884 has small-pox been so fatal as in the year under report. The numbers vaccinated during 1898–99 show a considerable increase, whilst there is, at the same time, an improvement in the percentage of successful cases in primary vaccination. In Rangoon alone, of all the towns, is there any very marked decrease in the numbers vaccinated. This decrease the Health Officer is inclined to regard as more apparent than real, and due to the fact that the accuracy of the returns of vaccination in 1896–97 and the previous years is open to grave doubt. The number of fever deaths was the highest yet recorded. This high mortality from fever may have been, in part, due to better registration, and also in part to growth of population since last census. Up to the end of the year only one case of plague, and that an imported one, had appeared in the Province. A sanitary engineer was appointed for the Province from the beginning of the year. Provided adequate funds are placed at his disposal, there should be ample scope for his services in the new and rapidly progressing Province of Burma.

25th May, 1900.

No. 6.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of the Central Provinces for 1898.

As the previous year of famine and sickness was the most disastrous to life of any hitherto recorded, so was the year under review the healthiest "which the Province has known during the past quarter of a century." The mean rainfall was 50·89 inches, or only 0·87 below that of the last 32 years. But from this statement no conclusion regarding the effect of the rainfall on the harvests of the Province, as a whole, can be drawn. In the Jubbulpore district, for example, "the rainfall was well distributed, and there were breaks at convenient intervals which benefited the *kharif* crop." As a consequence of the favourable rainfall, food was cheap, pressure was removed from the poorer classes, and the health of the people improved. Yet, in the adjoining district of Damoh, in the same division, "though the rainfall was heavy, it was not seasonable, and consequently did not do as much good to the crops as the monsoon of the year previous, but it benefited the rice crop, of

which there was a bumper harvest." The useful summary of the meteorology of the year given by the Sanitary Commissioner shows that the several districts of the Province were very differently affected by the season's rainfall; but that, whilst some crops partially failed, others succeeded, and as the general result, the food supplies were more plentiful and much cheaper than in 1897.

2. The *registration of vital statistics*, whilst continuing to be effected as heretofore, was extended to and carried out in *Zamindari* tracts with greater accuracy than had been previously possible. The Sanitary Commissioner has, however, considered it inexpedient to include the statistics from these tracts in the year's returns, as their general accuracy is still open to question, and the combined figures could not be conveniently used for the purposes of comparison with those of previous years. The time of taking the next census might be a convenient period from which to commence the incorporation of the vital statistics of the *Zamindari* tracts with those for the rest of the Province. Up to and during the year 1895, the population, since the taking of the census in 1891, normally increased from 9,531,560 to 9,718,030. From 1895, a series of calamitous seasons rapidly reduced the numbers, until, in the year under review, the population is estimated to number only 9,076,626. This estimate is arrived at by adding to, or subtracting from, the population figures of each preceding year, the annual number of births in excess, or in defect, of the annual number of deaths. It is not improbable that the reduction in the population numbers may be even greater than the estimate. It is certain that, during the time when distress was most acute in the Central Provinces, many of the inhabitants migrated into other provinces in quest of the means of subsisteuce. In this way, emigration may have had a not unimportant influence in bringing about a considerable, although not accurately known, reduction of the population below the estimated number.

3. The course of the *birth-rate*, when followed month by month throughout the year under review, is seen to be strikingly similar to that observed in the other provinces simultaneously afflicted by famine. During the first seven months, the number of births continued to be far less than the number in the corresponding months of the preceding year; during the last five months, on the other hand, under the influence of the better times which set in towards the end of the previous year, the number of births shows a remarkable increase over the number in the corresponding months of 1897. The effect of this increase in the birth-rate in the last months of 1898 was not only to compensate for the deficiency in the first seven months, as compared with the corresponding months of the previous year, but to bring about an excess of 29,203 in the totals for the year over the totals for 1897. "There was marked evidence in the birth returns," writes Colonel Hutcheson, "that the generative and recuperative power of those whose constitutions were not injuriously affected by want and privation, became active towards the close of the previous year and increased in the early months of 1898 to such an extent that the birth-rate during the closing months of the year under report became abnormal, so much so, that in the last quarter the number of births far exceeded any previous record." The birth-rate of 29·91 per 1,000 of population, recorded for the year, must be considerably lower than the real birth-rate, if the last census figures are used for working out the ratio. For, since the census was taken, the population had decreased by close upon half a million; and, to obtain the true birth-rate, the number of births should be calculated on the reduced population numbers of the year recording the births, and not on the higher population numbers of the census year.

4. The remarkable improvement in the health of the population of the Province may be estimated from a comparison of the *mortality* in the year under review with that recorded in 1897. In the latter year the deaths numbered 658,822, giving a ratio per 1,000 of population of 69·34; in the year under report they numbered 230,907, giving a death-rate of 24·30. In addition to the influence of a return of prosperity upon the public health in reducing the recorded death-rate, there were other causes operating in the same direction. In the case of the deaths, as in the case of the births, the population furnishing them was nearly half a million less than the census population on which the death-rate is calculated. Moreover, during a year of privation and distress the sickly and feeble, the very young and the very old, suffer disproportionately to the robust and those in the prime of life: the former disappear, leaving a population weeded of its weak and sickly members, and consequently with a higher average expectation of life. The low birth-rate of the year, also, doubtless contributed to a lessened mortality. The birth-rate of 29·91, although higher than that recorded in the previous year, was far below the birth-rate recorded for the decennium 1881–90, which was 41·56 per 1,000 of population. As a rule, to which, however, there are exceptions, a high birth-rate accompanies a high death-rate. The enormous death-rate of 400·00 amongst children under one year of age recorded in the previous year fell to 210·58 in the year under review. These figures illustrate the truth of the statement that the tendency to death is proportionately greater amongst the very young than amongst those of riper years; and consequently, that a population containing a high ratio of the very young, or in other words, a population with a high birth-rate, might be expected to record a high death-rate. If the examination by Native Superintendents of Vaccination of the entries of births and deaths in the registers kept by the *kotwars* and police was thorough, its results would afford strong evidence in favour of the accuracy of the registration of vital statistics in the Province. In the 3,989 villages inspected, the *kotwars* had recorded 40,413 births and the police 40,171; whilst the number found by the Native Superintendents was 40,525. One would like to know what method was adopted by the Native Superintendents for checking these entries. The only effectual method is believed to be that of making a house-to-house inquiry, a tedious and laborious proceeding which few have the time and patience to carry out thoroughly. The number of persons convicted for breach of the municipal byelaws, or not reporting births and deaths, during the year was only 184, as compared with 252 in the previous year.

5. *Chief Causes of Mortality.—Cholera*, which carried off 57,131 of the inhabitants of the Province in the previous year, had only seven deaths attributed to it in the year under report. The Central Provinces are thus seen to have shared in the immunity from this disease, which was so marked a feature of the sanitary history of the year throughout India.

6. The first case of *plague* reported in the Province was one introduced from Bombay, which ended fatally on the 31st December, 1896. From that date up to the 15th December of the year under review the total number of cases imported into the Province is stated to have been 19. Notwithstanding the importation of a succession of cases in 1897 and 1898, it was not until October of the latter year that the first indigenous case was detected. "At the end of that month the disease was communicated by a traveller from Bombay to a person residing permanently in Khandwa." Up to the end of the year under review, 125 fatal indigenous cases of plague were recorded.

7. Of *small-pox* deaths there were 926, as compared with 3,641 in the previous year and with 7,747 in 1896. Although there has thus been an abatement of the epidemic, the record of 65 deaths from the disease in December shows that it still lingered in the Province. Of the 926 deaths, 218 occurred amongst children under one year of age. Vaccination made good progress during the year 1898–99, showing an increase in the number of operations by all agencies, for the entire Province, of 50,551 in excess of the number for the previous year. But considerable part of this excess was due to the greater number of revaccinations performed. Notwithstanding that the season's work shows a satisfactory improvement over that of the previous year, and that much of the ground lost during the period of scarcity and famine has been recovered, the figures are still below those of the ante-famine years. But, as the Sanitary Commissioner points out, the decrease of the population during the three years 1896–98 must not be lost sight of in a comparison of the numbers vaccinated during the year under review and the years prior to 1896. This shrinkage of the population, estimated at close upon 650,000, comparing the population numbers for 1898 with those for 1895, would necessarily be attended by a substantial reduction in the number of persons available for vaccination. The percentage of successful cases in primary vaccination was 96·00, and was but slightly less than the percentage for the previous year. The percentage of success, 82·22, in revaccination, is, as usual in this Province, very high; but shows a considerable decrease as compared with that recorded for the previous year. Strict scrutiny would probably have shown that some of the vaccine vesicles returned as "successful" by the vaccinators in revaccination cases deviated more or less from the genuine Jennerian type. If this should not prove to be the case, the high percentage of success might suggest incomplete or imperfect primary vaccination. The use of animal lymph is superseding that of humanised lymph. During the year under report, 270,739 operations were performed with animal lymph. Colonel Scott Reid, who writes the Vaccination Report, says :—"A trial was also made of glycerinated lymph, but the results were unsatisfactory and not in accordance with those alleged to have been obtained in other countries." He adds :—"The virus when issued in this medium (glycerine) appears to be fairly active, but evidently soon deteriorates, probably due to the introduction of other organisms from want of scientific cleanliness in carrying out the method of preparation. I do not recommend a repetition of the experiment, and consider that the present mode of vaccinating direct from the calf is the most effectual yet tried."

8. Of the other chief diseases, *fever*, *dysentery*, and *diarrhœa*, it need only be said that the deaths from the first of them fell from a total, in the previous year, of 389,335 to 155,797, or to less than half; and that the deaths due to the last two diseases fell from 81,092 to 11,722, or to about one-seventh. The remarkable decrease in the mortality from those scourges of the famine-stricken, dysentery and diarrhœa, is a clear indication of the return of more prosperous times.

9. *Sanitary Works.*—Of these, perhaps the most important was the completion of the Jubbulpore waterworks. The total expenditure towards their completion fell but a little short of two and a half lakhs of rupees. Scarcely less important than the water-supply of the city of Jubbulpore is its drainage, now being proceeded with. In Annual Form No. XI., appended to the Report, we find the remark regarding Jubbulpore :—"Underground drains are blocked up and the subsoil water is gradually rising." This rising of the subsoil water is the usual consequence of introducing into a town a water-supply without at the same time providing effectual means of removing it after it has served its uses. Madras and Bombay are examples of the evil effects on the health of the inhabitants of cities, resulting from the incomplete removal of the water introduced into them. Jubbulpore is the second largest city in the Central Provinces, and its death-rate for the exceptionally healthy year under review was 30·23; whilst for the previous five-year period it was 49·89 per thousand of its population. Minor sanitary improvements effected during the year in other municipal towns of the Province are noted in Section IX. of the Report. After a series of disastrous seasons, it was not to be expected that funds would be available for the prosecution of sanitary works on an extensive scale.

10. No new villages were brought under the provisions of the *Village Sanitation Act* during the year. The list of those to which the Act has been extended is not a long one, but short as it is, there are not a few villages, such, for example, as the nine in the Jubbulpore district, in which "no steps appear to have been taken to enforce the provisions of the Act." As an illustration of the difficulties and dangers which the sanitary reformer has to face when he endeavours to introduce improvements amongst the people of India, some facts, gleaned from the Report by the Deputy Commissioner of Chanda, are not without interest. Referring to the two villages under the Act in his district, he remarks that :—"Like the villages under the Mukaddam rules, he found that in these villages, also, the well-to-do were utilising the services of the Conservancy staff, which is provided from the general funds, for clearing their own private latrines." Needless to say, this practice was at once stopped by the Deputy Commissioner; but its existence may be taken to offer some indication of the sense of their duty towards their poorer neighbours occasionally entertained by the well-to-do in Indian villages. Of the Sanitary Board, the Chief Commissioner remarks that it met as usual during the year, but that the work done by it was of necessity much restricted. "In 1898 both money and labour were scarce." The preparation of sanitary maps and the formation of sanitary circles are engaging attention. The Chief Commissioner observes with regret that virtually nothing had been done towards writing up the Village Note books prescribed by the Government of India; but he desires that the matter may receive attention during the approaching cold weather.

11. *Summary.*—The sanitary history of the year furnishes an example of the remarkable powers of recuperation possessed by the Province from the disastrous effects of famine and pestilence. The birth-rate of the latter months of 1898 was almost double the rate for the corresponding months of its predecessor, showing that the cessation of hard times towards the end of 1897, and the return of prosperity, exercised an immediate stimulus on the fecundity of the people. The death-rate diminished to about one-third of that recorded for the previous year. Cholera was practically absent. Plague, although repeatedly imported into the Province, failed to obtain a footing among the indigenous population until towards the end of the year. The epidemic of small-pox, which had carried off many thousands of the inhabitants during the three previous years, greatly abated, and a total of only 926 deaths from the disease was recorded. Vaccination recovered much of the ground which it had lost during the previous years of famine and distress; but the numbers vaccinated were still below those recorded in the ante-famine years. Animal lymph is being largely substituted for humanised lymph; and the Sanitary Commissioner is of opinion that the former is best used direct from the calf. The experience of the use of calf lymph mixed with glycerine as a preservative has not been favourable. The number of fever deaths recorded was only 155,797, as compared with 389,335 in the previous year; whilst those scourges of the famine-stricken, dysentery and diarrhœa, had attributed to them only 11,722 deaths, as compared with 81,092 in the preceding year. The depletion of the resources of the Province by the vast expenditure incurred in famine relief, retarded the prosecution of sanitary works on an extensive scale. The most important sanitary work of the year was the completion of the Jubbulpore waterworks. Little substantial progress was made in the working of the Village Sanitation Act during the year. The Chief Commissioner notes with regret that virtually nothing was done towards writing up the prescribed Village Note Books.

No. 7.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Assam for 1898.

Unlike 1897, which was a year of exceptionally great sickness and mortality, the year under review was one of average healthiness. From the summary given of the main meteorological features of the year in the districts for which *data* are available, it appears that in two of them, Cachar and Goalpara, the temperature of the year did not much deviate from normal; whilst in the third district, that of Sibsagar, it was much higher than usual. In all three districts, but to a different degree in each, the rainfall was short of the average. Whilst in Cachar barely half the average fell, and in Sibsagar 12 per cent. less than the average, in Goalpara the fall was only a little below normal. In two of the three districts food was cheap and in the third cheaper than in the previous year, but still dear. The difference in the price of food grains in the different districts was great. Whilst rice sold for 9 seers and 9 chittacks per rupee in Cachar, it sold for 12 seers and 14 chittacks in Goalpara; and whilst only 8 seers and 14 chittacks of wheat could be bought for a rupee in the former district, 15 seers and 11 chittacks could be bought for the same sum in the latter. Such differences in the price of food grains in the same province seem to point to difficulties and cost of transport. In Cachar, with a rainfall of barely half the average, and food cheaper than in the previous year, although still dear, the death-rate fell to about half the rate recorded in 1897. In the other two districts of Goalpara and Sibsagar, the one with a rainfall considerably, and the other with a rainfall slightly, below the average, and both with cheap food, the death-rate fell by nearly a fourth in the former and by more than a fourth in the latter.

2. *Registration of Vital Statistics.*—The population of the Province, according to last census figures, is 5,021,084. Births and deaths are registered in the plains districts of the Brahmaputra and Surma Valleys, as well as in certain selected areas in the hilly parts of the Province, including the station of Kohima. Including Kohima and the selected areas in the Garo Hills, the tracts in which registration of vital statistics is not yet in force, have a population, according to last census, of 455,749. Registration is still very backward in most parts of Assam, but more especially so in the districts of the Brahmaputra Valley, where the village headmen are responsible for the record of births and deaths, but receive no remuneration for the performance of this duty. In the districts of the Surma Valley the work of registration is better done. In these districts births and deaths are reported by paid village watchmen. In the Brahmaputra Valley the district of Goalpara is an exception to the rule that registration in the districts of that valley is entrusted to the *gaonburas* or village headmen. In Goalpara the *chaukidars*, or village watchmen, record births and deaths, with the result that the work is more efficiently performed than in any of the other districts. Under this *chaukidari*, or village watchmen system, of collecting and recording vital statistics in other Indian provinces in which it is in force, registration has greatly improved, and now furnishes in many of them figures on which reliable conclusions regarding the influences which affect the public health may be arrived at. Until registration by unpaid *gaonburas* is replaced by the *chaukidari* system, which gives so good results in Goalpara, or some other of equal or greater efficiency, there seems to be little ground for hope that an approximately accurate record of vital statistics will be secured. The Chief Commissioner writes: "Considering that the figures are calculated upon the census of 1891, and that the population, at least of foreigners, has enormously increased since that date, the general result shows that the work of birth registration is very imperfectly performed."

3. It was only to be expected that, immediately following 1897, a year of unprecedent sickness, the year under review would record a low *birth-rate*. From a ratio *per mille* of population of 32·59 it fell to 29·46, and was the lowest recorded in any province in India except Madras, in which latter

registration of vital statistics continues to be very defective. In the district of Goalpara the highest birth-rate in the Province was recorded, and in Nowgong the lowest. In the former this rate was 38·18, and in the latter only 18·66. In Goalpara the higher birth-rate is no doubt partly due to better registration; but the difference in the system of registration would probably not by itself account for the birth-rate of Nowgong falling short of that of Goalpara by more than half. The low birth-rate of Nowgong is no doubt, in part at least, due to the fact that the district "is the home of *Kalá-ázár*, and notoriously the unhealthiest in the Province."

4. The *death-rate* fell from a ratio of 50·61 per thousand of population in the previous year to a ratio of 36·15 in the year under review, but was still the highest recorded in any province of India. Nowgong records the highest death-rate, 47·25. In this instance its vital statistics, however defective they may be, are in agreement with the well-known position which the district occupies as the most unhealthy in the Province. If the registered numbers of births and deaths bear any approximation to the actual numbers, the depopulation of Nowgong must be in course of speedy accomplishment, unless the excess of deaths over births is being made good by the influx of immigrants. During the year under review 16,260 deaths were registered against only 6,421 births. For the Province as a whole the recorded number of deaths exceeded the recorded number of births by 33,638. Whilst the registration of vital statistics is still so imperfect, it would be unsafe to draw conclusions from these figures as to the increase or decrease of the population of the Province; but it is certain that, in the words of the Chief Commissioner, the population, at least of foreigners, has "enormously increased" since last census. Whether there has been an increase of the indigenous population is a question which may receive an answer when the next census is taken. Until the record of vital statistics is effected with some approach to accuracy, many important points bearing on the health and progress of the population of the Province must remain obscure.

5. *General History of the Principal Diseases.*—There was a marked decrease in the mortality from *cholera*. The number of deaths from this cause fell from 33,240 in the previous year to 11,149 in the year under report. The excessive cholera mortality amongst immigrant coolies coming up the Brahmaputra to work on tea gardens shows a remarkable decrease. In 1897 the deaths recorded amongst this class on steamers and at the coolie depôts numbered 1,121; in the year under report the number was 84. But this decrease was, in part at least, due to the circumstance that "the flow of immigration was much less in 1898 than in the two previous years." The Chief Commissioner adds: "But there can be no doubt that this satisfactory decrease in mortality was largely due to the exertions made by the Governments of Bengal and Assam to improve sanitary arrangements in the journey from the recruiting districts." It should not, however, be overlooked that, from whatever cause or causes, the year 1898 was not what may be called a "cholera year" throughout India. The disease was almost everywhere more or less in abeyance. The conditions to which its general decrease was due must also have been general in their nature and incidence. No doubt local sanitary arrangements would, as usual, have their effect in controlling outbreaks of the disease, but over and beyond these, some far-reaching and powerful influence must have been in operation to account for the marked abeyance in which cholera remained during the year throughout India.

6. The mortality from *small-pox* decreased from a ratio of 1·08 in the previous year to a ratio of 1·03 in the year under report. More than half of the small-pox deaths took place in the single district of Nowgong, in which the death-rate from this cause was 8·34 as compared with the provincial rate of 1·03. In his report for 1897, the Sanitary Commissioner, Colonel Stephen, predicted that a severe epidemic of small-pox would probably occur in Nowgong during 1898, in consequence of the unprotected condition of its population, who have a bigoted objection to vaccination. During the vaccination year 1898–99 there was a serious falling-off in the number of vaccine operations. Primary vaccinations decreased from 272,707 to 237,088. In the district of Sylhet, in which the largest decrease is recorded, "this result is attributed to a very severe outbreak of malarial fever in 1897, which caused a lowering of the general stamina of the population and a high rate of mortality amongst children, together with a decrease in the birth-rate in that year." The percentage of success recorded in this Province is, as usual, very high. In primary vaccination, according to Statement No. 1 of the Vaccination Report, the percentage was 98·35, and in revaccination 93·78. Both percentages are high, but that claimed in revaccination cases is incredible, except on the supposition that the protection conferred by the primary vaccination of those subsequently revaccinated was incomplete. Colonel Carr-Calthrop personally inspected a very large number of cases of vaccination during his tours, and, as a result of his observation, is of opinion that the number of cases reported as successful is too high. The officers in the best position to control the records of the vaccinators, and to see that only cases which fulfil all the conditions of genuine vaccination are returned as successful, are the Civil Surgeons. If revaccinations were subjected to the same tests, which have in Berar, for example, reduced the percentage of success to 23·1, it can hardly be believed that a percentage of 93·78 would be attained in Assam. The remarkable success which attends the use of calf lymph mixed with glycerine and water, and stored in capillary glass tubes, has nowhere else been attained in India. In the North-Western Provinces, after remarking that calf lymph in tubes, unmixed with any preservative, has not good keeping qualities in the climate of the North-Western Provinces, the Sanitary Commissioner adds:—"Very thorough supervision and a training in antiseptic methods far in advance of that given to vaccinators are required in the preparation of lymph preserved by admixture." In the Report of the Madras Presidency we read:—"As usual, fresh animal lymph shows the greatest percentage of success, viz., 97·6, then comes vaccine sent out between glass plates without any preservative, then lanoline paste, and lastly glycerine with 95·9, 88·0, and 82·4 respectively." Yet, in Assam, with calf lymph mixed with glycerine and water and issued in capillary glass tubes, the percentage of success recorded in primary vaccination, for the Province as a whole, is 98·35. The Vaccination Departments in other provinces might do well to study the method of supplying calf lymph, which gives so excellent results in Assam. In that Province arm-to-arm vaccination has been practically abandoned everywhere, and calf lymph, prepared and preserved as described, is distributed to the vaccinators of the several districts from a central bovine depôt.

7. Fever, including *Kalá-ázár*, was much less destructive than in the previous year : the death-rate fell from 28·74 per thousand of population to 20·90. In the two districts of the Surma Valley the decrease was especially great. In the Cachar district the fever death-rate in the previous year was 35·30, and in the year under report only 15·34. Accompanying this subsidence of fever mortality in Cachar, "barely half the average rainfall" was recorded in that district during the year under review. Probably there was some intimate, although not clearly understood, connection between the lessened rainfall and the lessened fever mortality. In the opinion of the Sanitary Commissioner, the fatal form of fever known under the name of *Kalá-ázár* appears to be gradually dying away from the Province as a whole. If the disease should follow the same course as that taken by the Bardwan fever epidemic, which it is said closely to resemble, its disappearance from Assam may perhaps take place in somewhat the same manner as the disappearance of the similar, if not identical, type of fever from Bengal. The endeavour to place quinine within reach of the people in remote parts of the Province meets with success. From a record of 2,181 packets, each containing 102 five-grain doses, sold in the previous year, the number has increased to 3,750 packets in the year under report.

Sanitary Works.—"No work of special importance was undertaken," writes the Chief Commissioner, "nor is it likely that in Assam, where the towns are so small, sanitary works of any magnitude will be undertaken for many years to come." But a great number of smaller improvements were made in many places. These improvements in rural areas consisted chiefly of the construction and repair of wells, and the excavation and deepening of tanks. The method of disposal of night-soil by trenching is adopted in all the municipalities except Sylhet ; but one great obstacle to its complete success is the rooted prejudice against the cultivation of the trenching grounds. This prejudice has existed and gradually disappeared in other provinces under the influence of the profits accruing to those who overcome it.

9. *Summary.*—In contrast with its predecessor, which was a year of exceptionally great sickness and mortality, 1898 was ordinarily healthy. The rainfall in the three districts for which records are given was, in one of them, barely half of the average ; and in the other two considerably less in the one and slightly less in the other than the average. Preceded by a season of unusual sickness, the year under review records a birth-rate the lowest of any province in India, except Madras. The births were fewer than the deaths by 33,638. But there is good evidence to show that, owing to defective registration, a considerable proportion of the births annually remains unrecorded. Until the system of registration of vital statistics by unpaid village headmen is replaced by some such system as that in force in the Surma Valley and in one district of the Brahmaputra Valley, it is hopeless to look for much improvement in the record of births and deaths in Assam. The death-rate of the year fell from a ratio per thousand of population of 50·61 in the previous year to 36·15 in the year under review, but was still the highest recorded in any province in India. Cholera deaths were fewer by nearly two-thirds than in the previous year. The decrease in the number of deaths from cholera amongst immigrant coolies was a satisfactory feature of the sanitary history of the year. No doubt the improved sanitary arrangements made in connection with the transport of the coolies from the districts in which they were recruited to the tea gardens in Assam helped to reduce the mortality from cholera ; but it should not be overlooked that 1898 was not what is called a "cholera year," and that general, if little understood, influences appeared to keep the disease in comparative abeyance all over India. Small-pox was less fatal than in 1897. There was a serious falling-off in the work of the Vaccination Department, but remarkable success attended the system of supplying calf-lymph mixed with glycerine and water, and stored in capillary glass tubes. The use of humanised vaccine lymph has practically been abandoned in Assam. The percentage of successful cases in primary vaccination reached the high figure of 98·35, whilst in revaccination the almost incredible percentage of 93·78 is recorded. The Sanitary Commissioner from personal examination of a large number of cases is inclined to think the recorded percentage higher than it should be. Fever, including that specific form of it known as *Kalá-ázár*, appears, the Sanitary Commissioner thinks, to be gradually dying away in the Province. No work of special sanitary importance was undertaken during the year.

No. 8.

Memorandum by the Army Sanitary Commission on the Medical and Sanitary Report of Coorg for 1898.

The total rainfall for the year measured 109·35 inches, as compared with 134·04 in the previous year. The largest amount of rain fell, as usual, in June, July, and August. The price of the staple food-grains, common rice, and *ragi*, but especially the latter, was higher than the average of the quinquennial period 1893–97. The mortality of the year exceeded that of any other prior to 1897—the most unhealthy year on record.

2. *Vital Statistics.*—Following a very unhealthy year, it was only to be expected that 1898 would show a low *birth-rate*. The number of births registered fell from 3,503 in the previous year to 2,795, and only slightly exceeded half the number of deaths. In Coorg, the number of births is generally less than the number of deaths, a peculiarity which has frequently been explained to be largely due to the constitution of the population. To the extent of upwards of a fourth of its total the population is

made up of coolies from Mysore, who annually enter the Province without their families to work on the coffee estates. An additional cause is also, no doubt, the imperfect registration of vital statistics. In a hilly country like Coorg, with a scattered population, the improvement of registration will be no easy matter. The Civil Surgeon suggests that the report of births might be encouraged by the giving of a small reward to the person making the report; but the Commissioner is probably right in believing that, if the reward were "worth having at all," it might lead to the making of false reports to obtain it. Even were it desirable to introduce compulsory registration, the necessary village agencies for carrying it into effect are said not to be available.

3. The *death-rate* of 31·44 per 1,000 of the population was nearly the same as the mean of 31·07 for the previous five years; this mean being, however, abnormally high owing to the excessive death-rate of 50·03 recorded in 1897. An examination of the mortality records according to age will show that, in Coorg, instead of the number of deaths amongst children under one year of age being, as in other provinces, greater than the number recorded for any of the subsequent age groups, it is largely exceeded by the number of deaths amongst adults between 20 and 30 and between 30 and 40. The high death-rate amongst the groups aged from 20 to 30 and from 30 to 40 seems to confirm the truth of the observations recorded from year to year regarding the abnormal mortality amongst the coolies who enter the Province in quest of work. The same table shows that, according to sex, the deaths of males over 20 and under 50 exceed in number those of females of the same ages. Between the ages of 20 and 30 the number of males who died was 546, as compared with 397 females of the same age; and between the ages of 30 and 40 the deaths of males numbered 574 to 324 of females. These figures seem also to support the statement that many of the coolies who annually enter Coorg do not bring their families with them.

4. *Chief Diseases.*—Only eight deaths were attributed to *cholera* during the year, as compared with 106 in 1897. At the same time, the number of deaths from *small-pox* decreased from 59 in the former year to 22 in the year under review. In Coorg, as in other provinces threatened with, or attacked by plague, vaccination work suffered much from the suspicion that got about among the people that it was in some way connected with plague inoculation. So serious was the excitement among the people, owing to this groundless suspicion, that it was considered expedient to discontinue vaccination operations from November, 1898, until the following March. Needless to say that, as a consequence, the numbers vaccinated during the year show a large decrease. Whereas those vaccinated by the regular establishment in 1897–98 numbered 10,616, in the year under review they numbered only 5,283, or less than half. In addition, however, to these, 390 vaccine operations were performed at dispensaries by medical subordinates. The percentage of successful cases recorded in primary vaccination was 93·15, and in revaccination 80·93. The latter ratio of success is so high as to suggest either defective primary vaccination or the return of all cases as "successful" which showed any sign of local irritation following the operation. In Calcutta, the ratio per cent. of success attained in revaccination, during the same year, was 23·68 of the cases regarding which the results were ascertained. The extraordinary variations in the recorded ratio of success in revaccination in the different provinces of India seem to be incapable of explanation, except on the assumption that there is a wide difference of opinion amongst vaccinators as to what constitutes a successful revaccination. Calculated on the census population of the Province, 29·46 *per mille* were protected against small-pox during the year by vaccination, as compared with 59·51 in the previous year.

5. *Fevers*, as usual, were credited with having caused the great majority of the deaths. The number of deaths registered under this head was 4,676, as compared with 7,182 in the previous year, or a ratio *per mille* of population of 27·02, as compared with 41·50. The ratio was, however, higher than the mean for the previous five years, which was 25·06.

6. Fortunately, *plague* did not succeed in effecting an entrance into Coorg, although it prevailed in the adjoining districts of Mysore. How much of the immunity which Coorg enjoyed from infection was due to the measures taken to examine all persons entering the Province from infected localities cannot be exactly determined. The Chief Commissioner seems to attribute some share in the fortunate result to the fact that plague measures of a drastic nature were not enforced in Mysore city when this was seriously affected, and to the consequent absence of the panic and the dispersion of the inhabitants which elsewhere followed attempts to arrest the spread of the disease by forcible measures of segregation and disinfection. The absence of communication by rail with Mysore territory, the Chief Commissioner thinks, may also have contributed to safeguard the Province from plague invasion. Efforts at prevention were not limited to the defence of the frontiers by the establishment of observation camps with police and medical staffs for the examination of visitors from outside. "The planters, both European and Natives, were fully alive to the importance of preventing the plague getting hold on the Province. They almost all had their lines white-washed, well cleaned up, and their sanitation generally attended to." It is satisfactory to learn that the authorities, whilst watching the frontiers of the Province, do not neglect measures calculated to prevent plague obtaining a foothold should it succeed in getting through the outer defences. Against the probable introduction of plague, the President of the Sanitary Board said that, "dependant as Coorg is for its supplies from Mysore, the only measures were strict attention to the sanitation of towns, villages, and estates, and the strengthening of the Medical Inspection Staff."

7. *Summary.*—The year, judged by its record of deaths, was less unhealthy than its predecessor. The mortality from all the principal diseases showed a decrease. Immediately following an exceptionally unhealthy year, 1898 records, as was only to be expected, a low birth-rate. For reasons repeatedly explained, the birth-rate of Coorg is generally lower than the death-rate, and in the year under review was about half of the latter. Neither cholera nor small-pox prevailed in epidemic form. The work of the Vaccination Department suffered from the plague-inoculation panic, and had to be stopped for several months until the public excitement subsided. The numbers vaccinated

decreased by about half, as compared with the numbers vaccinated during the previous year. Although plague prevailed in the adjoining districts and town of Mysore, it fortunately failed to effect an entrance into Coorg. This result may to some extent have been due to the vigilance of those in charge of the observation camps established on the frontiers of the Province. The Chief Commissioner thinks the immunity enjoyed by Coorg may have been, in part, due to the absence of forcible plague measures in the city of Mysore, and to there being no communication by railway between Coorg and plague-infected areas.

25th May, 1900.

No. 9.

Memorandum by the Army Sanitary Commission on the Rajputana Sanitary, Vaccination, Dispensary, and Jail Report for 1898.

The year was a comparatively healthy one. The rainfall was deficient in the Ajmer-Merwara Division as well as in most other parts of Rajputana, and the crops suffered ; but owing to facilities for import from more fortunate provinces the prices of food grains varied little from normal. If the deficiency of the rainfall may be taken as any measure of the extent to which the season's harvests suffered, the year must have been a calamitous one to the people dependent for their livelihood on agriculture. Whilst in Ajmer 23·29 inches of rain fell in 1879, and the average fall for the previous six years was 25·80, the total fall during the year under review was only 12·97, or about half. In Beawar the number of inches of rain measured was much the same as in Ajmer, and was 9·97 inches below the average. Besides the injury to the crops, the deficient rainfall caused a scarcity of the water-supply in most of the States of Rajputana. The influence of these conditions on the public health seems to have been what might have been anticipated ; the mortality from fevers was much less than in the previous year, and the mortality from dysentery and diarrhœa considerably greater. The exceptional dryness of the year was accompanied by lessened prevalence of malarial fevers ; and the scarcity of water, synonymous as a rule with its greater impurity, tended to increase the mortality from bowel complaints.

2. As in former years, the only part of Rajputana from which vital statistics are obtained which have any valid claim to be considered approximately accurate, is the Division of Ajmer-Marwara with its population of 542,358. Registration in the Native States of Rajputana, with their population computed at a total of from eleven to twelve millions, is still, in most of them, very defective, and in one at least is not even attempted. This need not be wondered at, if account is taken of the prevailing ignorance of the value of vital statistics, and the suspicion with which the registration of births and deaths is still regarded in many of the States. If the policy is persevered in of "constantly although cautiously" endeavouring to improve the system of collecting statistics, it is only a question of time, though possibly of a long time, until the statistics of the Native States are brought into line with those of the Ajmer-Merwara Division.

3. The *birth-rate* recorded in Ajmer-Merwara fell from a ratio per 1,000 of population in the previous year of 33·69 to 29·73. When this rate, itself no doubt considerably below the actual rate, is compared with that recorded in the Native States, some estimate may be formed of what remains to be done in the latter before the record of their vital statistics can be safely used as data from which to draw conclusions regarding the public health. "The average birth-rate registered in all the States which furnish returns was 13·64 *per mille* of population, and the death-rate 12·34." The record of births of male children is less defective in these States than of female children, many of the people being "still averse to reporting female births, which, according to their ideas, reflect discredit on the family and household."

4. The *death-rate* in Ajmer-Merwara shows a considerable decrease as compared with that for 1897. In the year under report it was 22·13 per 1,000 of population, and in the previous year 24·68. The decreased death-rate of the year was chiefly due to less mortality from fever. From some of the other principal diseases, such as small-pox, dysentery, and diarrhœa, there was a considerably higher death-rate than in the previous year. In the Native States, on the other hand, taking the returns for what they are worth, a decrease and not an increase in the mortality from small-pox, dysentery, and diarrhœa, as well as from fever, was recorded.

5. In Rajputana, as throughout India generally, 1898 was what the Administrative Medical Officer terms a "non-cholera" year. Only a single death suspected to be due to *cholera* occurred in the Ajmer-Merwara Division. In the Native States, also, the disease was practically absent. The six deaths said to have been caused by it in the Bharatpur State are considered by the Administrative Medical Officer to have been due to some local insanitary condition or poison, and not to true cholera. Other 14 fatal cases were reported from Bundi ; but as registration has only been attempted for the first time in that State in the year under review, much reliance need not be placed on the accuracy of the report. The unusual immunity from cholera enjoyed by India during the year 1898 is remarkable, and, as we have observed in other memoranda, was probably due to some general cause or causes affecting the whole county. In the preceding year the deaths attributed to cholera in Rajputana numbered 1,514.

6. *Small-pox* was nearly three times more fatal in the Ajmer-Merwara Division during the year under report than in the previous year, the number of deaths having increased to 409 from 158. Vaccination, both in the Ajmer-Merwara Division and in the Native States, made good progress during the official year 1898–99. In previous memoranda we commented on the remarkably high record of

successful cases recorded in some of the Native States, and expressed some doubt as to the percentages being the genuine outcome of the ordinary vaccinator's operations. In the report under review it is stated, with reference to our remarks, that "the Administrative Medical Officer gave considerable attention to the high percentage of vaccination, and he has no reason to suspect irregularities." Taking as an example of the ratios of success recorded by some of the Native States, the ratio claimed by Kishnagarh, it is noted that, of the 2,607 cases of primary vaccination, 99·96 were successful, notwithstanding that Kishnagarh is one of the States described as "still very backward" in respect of vaccination. This backwardness must refer to the quantity, and not to the quality of the work. It is but fair, however, to state that the result of the examination of a large number of cases by Residency and Agency Surgeons, appears to support the Adminstrative Medical Officer's belief in the accuracy of the ratio of success claimed by the vaccinators.

7. The steps taken to keep *bubonic plague* from establishing a footing in Rajputana had, up to the end of the year, proved successful. So far, no indigenous cases had followed the entrance of imported cases; but the experience gained in other provinces does not favour a confident belief that this preliminary success will be followed by the permanent exclusion of the disease from a country, the borders of which are described as being "much exposed to an invasion of plague."

8. The record of sanitary defects and improvements shows that progress is being made in sanitation throughout most parts of Rajputana. The city of Jaipur, with a population of 158,905, sets an example to the other towns of the Province. In this exceptionally advanced city the water supply is described as being "sufficient and good." The latrine system has been improved during the year, and the conservancy system is working satisfactorily. Village sanitation is likewise beginning to receive some attention in most places; but until the villagers have become more enlightened, and have learnt at least such elementary lessons as the need for drinking pure water and breathing pure air if health and comfort are to be enjoyed, it may be wise to insist on the enforcement of no more energetic measures of sanitary improvement than those described in paragraph 64 of the Report. "Residency and Agency Surgeons have been encouraged to spend as much of the cold weather as possible in camp, where they have had opportunities of advising sanitary authorities in the sanitary measures which could be easily carried out. With the exercise of tact, patience, and judgment on the part of the medical officer the people can be prevailed upon to protect their water-supply, and do much to improve the sanitary condition of their surroundings, which would not easily be accomplished by Durbar orders."

9. In both Ajmer-Merwara and in the Native States the numbers of both indoor and outdoor patients treated at dispensaries show a considerable decrease as compared with the numbers for the previous year. This is only equivalent to saying that the year under review was healthier than its predecessor. The usual dryness of the year was accompanied by a marked decrease in the number of patients treated for fever and spleen affections. In keeping with these conditions there was a falling-off in the sales of quinine. The number of surgical operations, however, shows an increase from 62,004 in 1897 to 64,489 in the year under review.

10. The death-rate in the Ajmer jail rose from a ratio of 6·84 per 1,000 of jail population to 13·90; but even the latter rate cannot be considered a high one. The increased mortality is attributed to the fact that a comparatively large number of the convicts were old and in indifferent health at the time of admission. In the 20 jails in Native States from which returns were received, there was a marked decrease in the number of the admissions into hospital more especially, but likewise a decrease in the daily average number of sick as well as in the death-rate. This last fell from a ratio of 23·58 per 1,000 in the preceding year to 19·23. It is thus evident that the healthiness of the year had a marked effect in reducing the ratios of sickness and mortality among the prisoners as among the free population. Improvement in the management of the jails, no doubt, also contributed its share to the improvement of the health of the prisoners. Regarding two of the most unhealthy jails in the Native States the Agent to the Governor-General writes:—"The state of the existing jail at Banswara, like that at Dholpore, demands and has received close attention."

11. *Summary.*—The year was a healthy one. The deficient rainfall was unfavourable to the crops, but was accompanied by diminished fever prevalence and mortality. Except in the Ajmer-Merwara Division, the registration of vital statistics continues very backward. In many of the Native States no dependence can be placed on the ratios of births and deaths recorded. The ignorance of the people and the suspicion with which they regard the registration, more especially of births, will take time and patience to overcome; but constant though cautious endeavours are being made to improve the system of collecting vital statistics. Needless to say, the ratios of 13·64 births and of 12·34 deaths per 1,000 of the population of the Native States, recorded for the year under review, probably represent less than half the actual ratios. In Rajputana, as in the other provinces of India, cholera was in abeyance. The few deaths attributed to the disease, the Administrative Medical Officer thinks, may not have been due to true cholera. Small-pox was three times more fatal in the Ajmer-Merwara Division than in the previous year. Vaccination made satisfactory progress. The usual phenomenally high percentages of success claimed by the vaccinators of the Native States continue to be recorded; but the Administrative Medical Officer, who has given attention to this matter, says he has no reason to suspect that they are due to irregularities. Although several cases of bubonic plague were imported into Rajputana, no indigenous case of the disease occurred up to the end of the year. Substantial progress in sanitation is being made in most parts of Rajputana. The attendance of patients at dispensaries fell off during the year, which is equivalent to saying that the year was healthier than its predecessor. The health of the prisoners, like that of the free population, was better than in 1897.

No. 10.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Madras for 1898.

The Report of the Sanitary Board, which precedes that of the Sanitary Commissioner, gives brief details in an Appendix of the Municipal and Local Funds works, with their plans and estimates, dealt with by the Board during the year. The total estimated value of these works falls somewhat short of five lakhs of rupees. The type designs being prepared and issued by the Board for such buildings as slaughter-houses, vaccine depôts, latrines, &c., should prove useful guides to municipal and local bodies. Anyone may see that much money has hitherto been spent in India on buildings defective in principle and ill-adapted for their purpose, because the needful expert sanitary and engineering knowledge may not have been available, or was not taken advantage of, when the buildings were being designed. The example set by the Madras Board, of issuing type designs of buildings of the nature mentioned in paragraph 18 of its Report, might be usefully followed in other provinces in which the Municipalities and District Boards may not already be in possession of such designs.

2. The year under review was favoured by a generally satisfactory rainfall. Whilst the quantity of rain registered during the south-west monsoon, 25·70 inches, was almost up to the decennial average of 25·84, the fall during the north-east monsoon was 6·13 inches in excess of the decennial average of 14·94 inches. Yet, the prices of food grains fell little below those which ruled during the previous year of scarcity or famine, and were greatly above the prices of 1896, as well as the average of the 10 years ending with 1895. In the case of the staple grain, *ragi*, there was no fall whatever. A glance at the table at the end of paragraph 2 of the Report, shows a general, though somewhat irregular, rise of prices since 1883. The Sanitary Commissioner, whilst considering that it would be going beyond the scope of his report to enter into the various factors which have brought about this rise in the price of food-grains, thinks that, notwithstanding the adverse effect of the rise on certain sections of the community, "for the majority it implies a wave of prosperity, that will, in due time, bear with it in its advance the temporarily suffering minority." Amongst the indications which lead him to form this hopeful forecast, he mentions the decided tendency to increase of wages of the lower classes, and no diminution of the area under cultivation, no excess of emigration, great increase of capabilities of interchange of products by rail and sea, the general accession of manufactories of raw products, and increasing exports of seeds and grains. One factor likely to influence prices of food-grains is the ever increasing pressure of population. There may be no diminution of the area under cultivation, but unless there is, on the contrary, a very large expansion, the increase of the population of the Presidency since the census was taken in 1891 by over two millions, comparing the census with the estimated figures, can hardly fail to exercise a decided effect on food prices. The population according to last census was 35,641,828 : it is now estimated to be 37,715,417.

3. The *birth-rate*, estimated upon the last census figures, was 27·4 per thousand of the population, as compared with 28·7 in the preceding year. This decrease is attributed by the Sanitary Commissioner, partly to the influence on fecundity of the famine conditions which prevailed in several districts during 1896–97, partly to marriages having been deferred as far as possible during the past three years in consequence of the expectation of "evil times" by the native population, and to imperfect registration. In some of the districts, registration of vital statistics continues to be very defective. In the districts of Malabar, with its population of over two and a half millions, the birth-rate recorded is only 18·6 per thousand of population, in Madura 22·7, and in Ganjam 22·9. In other words, approximately half the number of births probably remained unregistered in these districts. In municipalities the birth-rate was 34·9, as compared with 34·4 of the previous year. Obviously, registration of births is effected with much greater completeness in municipal towns than in rural areas.

4. The *death-rate* decreased from 25·4 in the previous year to 21·0 in the year under review. In some districts, such for example, as Ganjam and Malabar, the decrease was very great. In the former district a death-rate of 50·1 was recorded in the previous year and of only 22·1 in the year under report. This remarkable decrease was in considerable part due to the abatement of the violent epidemic of cholera, by which the district was ravaged in 1897. Whilst in that year cholera was credited with a death-rate of 12·5 per thousand of its inhabitants, the disease has practically disappeared in 1898, having recorded against it only 0·04. Small-pox was likewise very fatal in the former year, when it was responsible for a death-rate of 1·7; but, unlike cholera, it still continued to be the cause of great mortality in the year under report. In this latter, the recorded death-rate was 8·5. In addition to the decrease in mortality from these two diseases in Ganjam, the fever death-rate fell from 19·9 in 1897 to 11·3 in 1898. As regards Malabar, the decrease was due mainly to lessened mortality from cholera, the death-rate from which fell from 9·9 to 0·4. As in the case of births so in the case of deaths registration is carried out with a greater approach to accuracy in municipalities than in rural towns and villages. The average for municipalities was 31·9 *per mille* of their population, as compared with 19·0 recorded in rural towns. In some of these latter, such as Samalkot, Paramagudi, and Sendamangalam, towns of over 10,000 inhabitants, incredible rates are recorded. In the first-mentioned town the death-rate given is 8·1; and in the other two 9·2 and 9·8 respectively. In certain municipal towns, such, for example, as Dindigul and Bimlipatam, death-rates of under 20 *per mille* are recorded; showing that, even in these, registration is still far from being satisfactory.

5. *Chief Diseases.*—Although *cholera* was credited with less than half the number of deaths recorded against it in the previous year, the mortality caused by it was still high in the Presidency as a whole, and in certain districts excessive. During the year, 65,444 cholera deaths were registered,

giving a death-rate of 2 *per mille* of the population, as compared with 4·4 in the previous year, and with a decennial average of 2·1. The districts of Tanjore, Trichinopoly, and South Arcot suffered severely. The first of these records a death-rate from cholera of 6·7 and the other two 5·5 and 5·2 respectively. These districts "offer good facilities for the transmission of the cholera microbe from village to village by means of lengthy channels that are liable to contamination by reason of the insanitary habits of the people." It would have given more weight to this view of the transmission of cholera by means of a microbe had it been supported by statistics showing that the opening of those channels marked the commencement, in the tracts which they traverse, of a period of increase in the prevalence of cholera as compared with the period preceding their opening. If such statistics can be procured they would be of much interest and value. The fear is that, owing to the defective state of registration, they might not only be unreliable but misleading. Regarding the two municipalities which show the highest cholera death-rates, Palni and Nellore, the former recording a rate of 14·4 and the latter of 10·2 per thousand of population, it is stated that "the drinking water of Palni is subject to pollution"; whilst no remark is made about the water-supply of Nellore, except that two wells and four tanks were repaired." Neither of the towns is in one of the districts mentioned as being "the great irrigation centres of the Presidency." The large town of Trichinopoly has a pipe water-supply, although it is stated that a portion of the town is still supplied by the river Cauvery and its channels. The cholera death-rate in Trichinopoly was 7·3 *per mille*. The rural town which gives the highest cholera death-rate, 24·5, is, like Palni, in the Madura district. The Sanitary Commissioner shows by a table, in paragraph 32, that "had the populations of the 24 towns under the Cholera Rules for combating the disease been attacked at the same rate as those not subject to them they would have lost, during 1895 to 1898, 2,964 more lives than they actually did." Unfortunately, the utility of these rules is often greatly lessened by the inefficient way in which they are applied in municipalities; and the Government has drawn the attention of all collectors to the remarks of the Sanitary Commissioner on this point.

6. *Small-pox* caused 20,490 deaths, equal to a rate *per mille* on the census population of 0·6. The rate for the previous year was 0·7. In the district of Ganjam, which last year contributed more than two-thirds of the total number of small-pox deaths in the Presidency, the disease was again very fatal. Table No. XI. of the Appendix to the Report, which gives the deaths in districts exclusive of towns, shows that of a total of 19,699 deaths from small-pox in the 21 rural districts of the Presidency, Ganjam was responsible for 10,838, or considerably more than half. There were many difficulties in the way of effectually protecting the inhabitants of Ganjam against small-pox by means of vaccination: according to the Sanitary Commissioner, that district "presents a most unpromising field to the sanitarian." In none of the other districts can small-pox be considered to have been very fatal. During the official vaccination year 1898-99, the number of cases of primary vaccination shows a decrease of 149,433 and of 4,303 re-vaccination cases. The cause of so large a falling-off is said to be "probably mainly due to a widespread plague-inoculation scare." Among other reasons given to account for the decrease are the failure of the lymph supply in certain districts and absence on leave of vaccinators without substitutes. The first of the causes assigned was probably altogether beyond the control of the Vaccination Department; but for the provision of an adequate supply of good vaccine lymph and the maintenance of the staff at its full strength one would have expected the Department to be competent to make satisfactory arrangements. Accompanying this decrease in the amount of work there was a distinct fall in the percentage of successful cases. From 92·5 and 92·0 in the two previous years, this percentage fell, in the year under review to 89·5. A table is given in paragraph 8, showing the percentage of children under one year of age protected in proportion to the number of births. In districts, exclusive of municipalities, the highest percentage recorded was 66·8 in Madura; and the lowest 2·1 in Malabar. In many municipalities the number of children under one year of age who were vaccinated, considerably exceeded the recorded number of births. The municipality of Madura gives the highest percentage of 124·7, and that of Cuddapah the lowest percentage, 27·7. The explanation of the excess in the number of children vaccinated over and above the recorded number of births is doubtless to be found in defective registration of vital statistics, as has been suggested in the Government review of the vaccination report. The use of vaccine lymph taken from human beings has been discontinued entirely in Madras. "As in the previous year, all the operations were performed with animal lymph." As might have been expected, calf-to-arm vaccination gave by far the best results: 92 per cent. of the cases proved successful. Lymph preserved with glycerine gave the worst results, returning only 82·8 per cent. of successful cases. There is, however, an exception to this general experience. In the hands of the dispensary staffs and medical subordinates the results, as recorded in the table on page 17 of the Report, show that lymph "direct from the calf" proved successful in only 73·6 of the cases; and "glycerine paste" in 80·1 per cent. These results are so unusual that some inquiry might be made as to the mode by which the operators succeeded in bringing them about.

7. *Fever* mortality decreased considerably during the year under report as compared with the previous year. The death-rate from this cause fell from 9·0 to 7·5 *per mille* of population. The decrease was chiefly marked in districts that in 1897 had been affected with famine. "From this may be argued better nutrition and better resisting power to malaria of the people of these districts." The Sanitary Commissioner in paragraph 38, as the results of a careful inquiry, shows very clearly that in the town of Madras the returns were ingeniously manipulated during the prevalence of cholera and plague. When the former disease prevailed, there was increased registration under the head of "fever." The object of this was doubtless to prevent the troublesome inquiries which follow the occurrence of cases of cholera, and the extra work thrown on those who are obliged to make special and immediate report on the appearance of each case. Similarly, on the occurrence of plague in Mysore territory and the consequent exercise of greater vigilance on the part of the municipal sanitary staff as to "fevers," the number of cases of the latter fell off, whilst the number of deaths referred to "other causes" largely increased. Ordinarily, when a death is reported as having been caused by "fever," no further inquiry is considered necessary, and no further trouble given to the reporting agents; but fever being a prominent symptom in plague, when the latter disease appeared, all cases of fever were subjected to a strict scrutiny, with, for result, a diminution in the number of

cases registered under the head of "fever" and an increase under the head of "other diseases." By this easily-effected alteration, the registering agents no doubt trusted to be able to save themselves from the troublesome inquiries which, during the prevalence of plague, would follow the report of fever cases.

8. *Dysentery and Diarrhœa*, like fever, and probably from the same cause, the better nutrition of the people, were less fatal than in 1897, the death-rate attributed to them falling from 1·2 to 0·9 *per mille* of population. There can be little doubt that the mortality from these diseases in Madras, as elsewhere, is much understated, many of the deaths due to them being recorded under the head of "fever."

9. *Plague* was imported during the year into 96 localities in a total of 11 districts, including Madras; but in only 20 localities in five districts was it reported as indigenous. The observation of passengers arriving from plague-infected tracts, which commenced in 1897, was kept up during the year under review, and, in addition, a system of inspection of passengers arriving by road was established on the frontiers of several districts. Anti-plague inoculation was practised in accordance with M. Haffkine's method. It is stated that 5,685 inoculations were performed in the Madras town and 10,532 in the Presidency generally. One untoward consequence of these inoculations was the confusion of them by the people with vaccination. This resulted in what has already been referred to as a plague-inoculation scare, followed by a serious decrease in the number of vaccination operations performed during the year. "The result," writes the Sanitary Commissioner, "must be, in the end, a greater loss of lives by small-pox than can have been saved by anti-plague inoculation." In Madras, "evacuation of indigenously affected areas has been found, as in all epidemics of this disease that history has recorded, the best sanitary measure."

10. *Sanitary Works.*—The extension of the waterworks at Conjeeveram, at an estimated outlay of about half a lakh of rupees, was undertaken during the year. Four surveys in connection with water-supply were completed, and one drainage and five water-supply schemes were prepared and submitted either to the Sanitary Board or to Government. It can hardly be said that the list of important sanitary works of a permanent nature undertaken during the year is a long one. Want of the needful funds no doubt, as usual, restricted the number of such works. "Even the sanguine sanitarian," writes Colonel King, "finds at last that it is hopeless reporting to bodies that have no funds to bestow on the improvements he indicates."

11. *Summary.*—The year's rainfall was favourable. As a result there was some decrease in the price of staple food grains, except of *ragi*, which remained the same as in the previous famine year. The Sanitary Commissioner takes a sanguine view of the effect on the population of the continued rise in the price of food grains which has been going on for many years past, and gives his reasons for believing that it implies for the majority "a wave of prosperity that will in due time bear with it in its advance the temporarily suffering minority." A birth-rate of 27·4 was recorded, against 28·7 for the previous year. The decrease is attributed partly to the influence on fecundity of the famine conditions which prevailed in some districts during 1896–97, and partly to marriages having been deferred under the expectation of "evil times" in the near future. The death-rate decreased from 25·4 in the previous year to 21·0 *per mille* of the last census population. This decrease was, doubtless, largely due to the return of prosperity, better and more abundant food, and consequent increased resistance to disease. Registration of vital statistics continues, especially in rural areas, to be very defective; in municipalities it is much better, although still imperfectly carried out. Cholera was credited with a death-rate of 2 *per mille* of population, as compared with 4·4 in the previous year. In some districts the cholera death-rate was more than double the provincial rate, and in two municipal towns rates of 10·2 and 14·4 were recorded. Small-pox caused over 20,000 deaths, more than half of which took place in the single district of Ganjam. There was a large falling off in the number of vaccine operations, due mainly, it is stated, to a widespread plague-inoculation scare. Other causes also unfavourably influenced the season's work. Of these the most important were inadequate supply of good vaccine lymph, and absence on leave of vaccinators without the appointment of substitutes to fill their vacant places. All vaccine operations in the Presidency were performed with animal lymph. As was to be expected, fever and bowel complaints were less fatal than during the preceding year of scarcity and famine. Plague found entrance during the year into 96 localities in a total of 11 districts, but in only 20 localities of five districts was it reported as indigenous. In Madras, as everywhere else, "evacuation of indigenously affected areas has been found, as in all epidemics of this disease that history has recorded, the best sanitary measure." Sanitary works were carried out as far as the limited funds available would permit.

25th May, 1900.

No. 11.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Bombay for 1898.

The year under review was, in its main meteorological features, somewhat like its predecessor. The rainfall was not so heavy, but was up to the average and fairly uniformly distributed. Table A, on pages 31 and 32 of the Report, shows that, in the six districts selected as representing the Presidency generally, there was a marked fall in the prices of food grains as compared with the prices which ruled in 1897. In the case of the millets *juari* and *bajri* the fall was very great. The latter seems to be a staple food grain in all of the six representative collectorates; and its price was, in five

of them, only about half, or less than half, the price at which it sold in the previous year. In Belgaum the fall was not so great : 19 seers were sold for one rupee in 1897 as compared with 16 seers in 1898. The staple food grain *ragi* fell in price only from 16 to 18 seers per rupee. The fall in the price of wheat and rice was also considerable, although not to the same extent as the fall in price of the greater and lesser millets This cheapening of the staple food grains of the people produced a very decided improvement in the public health, as reflected in the marked decrease in the death-rate compared with that recorded during the previous year of scarcity or famine. The birth-rate having, of course, been largely influenced by the unfavourable conditions prevailing during the previous year, reflects to some extent, as was to be expected, those conditions, and, instead of an increase, shows a decrease.

2. The small European and Eurasian populations of the Presidency, numbering respectively, according to last census, 18,486 of the former and 8,519 of the latter, return approximately the same birth-rates as during the previous year, and considerably lower death-rates. Of the Europeans, 13 died of plague in Bombay city as compared with 20 in 1897, and one died of the same disease in Poona. Of the Eurasians, 22 died of plague in Bombay city and one in Poona, as compared with a total of 44 deaths from this cause in the preceding year. There was no death in the year under report in either community from cholera or small-pox.

3. For the Native population the *birth-rate*, which was 33·46 in the previous year, fell to 30·94 in the year under report, and was 5·1 below the mean for the ten years ending 1897. An examination of the monthly record of births shows that, during each of the first seven months of the year, the number of children born fell far below the number born in the corresponding month of the preceding year, and also of the mean for those months during the ten-year period 1888–97. On the other hand, the number born during each of the last five months was largely in excess of the number born in the corresponding months of 1897, and also of the mean of the corresponding months, excepting August, of the ten years 1888–97. We noted that the birth-rate took a similar course during the year in the North-Western Provinces, Bengal and Madras : the first months of the year showing a low, and the last months a high, birth-rate as compared with the rates for the corresponding months of the previous year. The provinces mentioned resembled each other in one particular : all suffered over a greater or less extent of their areas from scarcity or famine in 1896–97. It is reasonable to attribute in all of them like results to the operation of like causes. This has been done by the Sanitary Commissioners, who account for the low birth-rate in the first half of the year under review chiefly to the influence on fecundity of the hard times under which a large proportion of the people had to live until the return of prosperity in the autumn of 1897. Contrary to what was observed in the vital statistics of the neighbouring Presidency of Madras, the birth-rate recorded in urban circles in Bombay falls far below the birth-rate in rural areas. For the Presidency the recorded urban birth-rate is 24·05, and the rural rate 31·91. In Madras, the ratio of births *per mille* of population in town circles was 33·0 and in rural circles only 26·9, according to Statement No. 1, Appendix D, of the Sanitary Report for that Presidency. We have thus in the one Presidency, towns recording a comparatively high birth-rate, and rural areas an abnormally low one ; and in the other Presidency the towns recording a low birth-rate and rural circles a comparatively high one. It is more probable that these contrary results are due to defective registration of vital statistics than to difference of social or other conditions prevailing in the towns and villages of the two contiguous provinces. In Bombay, 11 of the 56 towns in the Presidency return birth-rates of less than 20 *per mille* of their populations. In some of the rural areas also, the birth-rates recorded would seem to indicate neglect of registration. This is, as heretofore, especially the case in rural circles in the Sind collectorates : the rural part of the Hyderabad collectorate records the incredible birth-rate of 15·47, whilst the urban birth-rate in the same collectorate is 39·62. The abnormally low birth-rate recorded in several of the towns of the Presidency during the year is attributed to the decrease of their population owing to the exodus caused by plague. Bombay and Poona are examples. The former records a birth-rate of 13·08 and the latter of only 10·83. In Bombay city, however, defective registration of births contributes, it is pretty certain, to the abnormal lowness of the birth-rate.

4. The *death-rate* of the year under review declined from a ratio per thousand of population of 39·84 to 29·16. To the return of more prosperous times the decrease was, no doubt, mainly due. There was a decrease under the head of fever alone of no fewer than 150,081 deaths. Cholera and small-pox were also in comparative abeyance. The only disease which by its increase tended to raise the death-rate of the year was plague : the deaths from this cause, which numbered 46,944 in the previous year, rose to 86,191. Under the heading "other causes" the deaths recorded show a remarkable increase. The Sanitary Commissioner thinks this may have been due to better diagnosis of the diseases causing death ; but coinciding as the increase does with increase of plague mortality, it seems probable that cases of fever which in ordinary years, when plague is absent, would be recorded under their proper heading, were transferred to the head of "other causes." Colonel King gives grounds for believing that such transfers were made in Madras, and under similar conditions they may have taken place also in the Bombay Presidency : in both cases deaths reported as due to fever, which is a prominent symptom of plague, being likely to give rise to troublesome inquiries, the reporting agents found it convenient to report fever cases under the head of "other diseases." At any rate, the return given in paragraph 96 of the Report seems to support such an explanation of the sudden increase of the number of deaths recorded under the head of "other causes." From 97,104 in 1895 the deaths under this heading have increased to 100,112 in the following year, and thereafter in the two plague years of 1897 and 1898 to 143,503 in the former of these two years and to 176,335 in the latter. No doubt there may be some gradual improvement in the differentiation of the causes of death, but progress in this direction can hardly be so rapid as the sudden growth of the numbers recorded under the heading "other diseases" would indicate. A high birth-rate is usually held to accompany a high death-rate. This may hold good in countries in which health conditions are fairly constant from year to year ; but in a country like India, the incidence of famine or pestilence, or both together, may completely upset deductions regarding the death-rate founded merely on a knowledge

of the birth-rate. An examination of the statement on page 17 is interesting from this point of view. Taking the town at the top of the list of death-rates, Belgaum records a death-rate of 106·76 for the year under review. The same town is near the bottom of the column of birth-rates, with a record of a ratio of only 13·05 births *per mille* of population. Hubli, with a death-rate of 69·09, has a birth-rate of 18·72; and the town of Bombay, with a death-rate of 64·03, records a birth-rate of 13·08. Many similar examples might be quoted. Faulty registration is generally called in to account for the startling contrasts which are detected between the vital statistics recorded for different places or different years; but as the Secretary to the Government says in his review of the Report:—"The times have of late been so out of joint" that comparisons with previous years, or between different places, are of little value. The truth of this is very clearly established by a reference to the table given in paragraph 47. Here we find, for example, urban Belgaum recording a death-rate of 39·42 in 1897, and a death rate of 87·60 in the year following. Conversely, urban Poona records a death-rate of 85·89 in 1897, and one of 25·66 in 1898.

5. *Chief Diseases.*—The deaths from *cholera* were fewer than in any year since 1890. Of the total 4,368 deaths from this cause, no fewer than 4,054 occurred in the Dharwar collectorate alone. During the previous year cholera caused 57,100 deaths, the highest number recorded in any one year since 1879; the two consecutive years 1897 and 1898 thus show, respectively, abnormally high and abnormally low cholera death-rates.

6. *Small-pox* appears to be held well in check by the efficiency with which vaccination is carried out in this Presidency. Only 1,834 small-pox deaths were recorded in the entire Presidency, or equal to a ratio of 0·1 per thousand of population. During the previous year of famine the death-rate did not exceed 0·2 *per mille* of population; whilst the rate for the decennium was only 0·21. The Sanitary Commissioner is justified in claiming that "these figures may be considered very satisfactory, and testify to the exceedingly good vaccination work which now for some years has been done in the Presidency." It would be a pity, after the efficiency of the Vaccination Department has thus been proved by the approximately complete fulfilment of the purpose for which it exists, if circumstances should compel the Government to weaken its strength by the temporary withdrawal for other duties of some of its most important members. "Vaccination has suffered both in quantity and quality owing to the absence of inspection and supervision by the Deputy Sanitary Commissioners, who are the mainstay of the Department, and without whom efficiency cannot be maintained." An examination of the returns shows that there has been a serious falling-off in the number of successful vaccine operations during the past two years. In 1895–96 the successful primary vaccinations numbered 683,044. They showed only a nominal decrease in the following year; but in 1897–98 they went down to 626,170, and now, in the year under review, to 579,144. Accompanying this decrease in the number of successful primary operations, there has been a decrease in the percentage of successful cases from 93·23 in 1896–97 to 92·84 in the year under review, although it should be acknowledged that the latter percentage is an improvement on the figures for 1897–98. The decrease in number of operations is not confined to primary vaccination; revaccinations fell from 78,156 in 1895–96 to 51,154 in the year under review. The causes which led to this serious decrease in the amount of vaccination work arose from circumstances beyond the control of the Department. "Work in all the districts was effected by the absence of Deputy Sanitary Commissioners and by their posts not being filled up by full-time officers. In some districts inspectors and vaccinators have been absent on plague duty." The decrease extends to all the districts except the Presidency circle, but is most marked in the Southern District, "where a low birth-rate for the last two years and a severe plague epidemic during the present year greatly interfere with work, which was also affected by the absence of some inspectors and vaccinators on plague duty." Animal lymph is used to a considerable extent in this Presidency, but most of the operations still continue to be performed with human lymph. The proportion in which these two kinds of lymph were used in the Central Registration district is shown in the table in paragraph 5 of the Vaccination Report. There were 129,759 operations performed with human and 30,450 with animal lymph.

7. The number of deaths recorded as due to *fever* include also the deaths from *plague*. The combined total from both diseases was 302,515 a number less by 150,081 than the previous year's total, and less than the decennial mean of 384,710. Excluding the 86,191 deaths from plague, the fever deaths number only 216,324, the lowest number referred to this cause for many years. In other words the year was a healthy one. Not only did the return of prosperity enable the people to regain and maintain their health, but the pressure of hard times during the previous year had doubtless caused the disappearance of many of the weakly, who might otherwise have struggled on to die in the year under report and swelled its death roll. The fever deaths recorded in 1897 numbered, including plague deaths, 452,596 against 302,515 in the year under review. There was also a striking decrease in the mortality from *dysentery* and *diarrhœa*, due chiefly, there can be no doubt, to the causes which brought about the decrease of fever mortality. The death-rate fell from 4·57 in the previous year to 3·02.

8. An examination of the death returns shows that *plague*, notwithstanding all the efforts to circumscribe its area, had effected an entrance into each of the collectorates of the Presidency, excepting two of the Sind Registration Circle. Yet, in only three of the collectorates was the mortality serious. The greatest number of plague deaths, 27,764, occurred in Dharwar; in two only of the other collectorates did the deaths number ten thousand. So far, the increase in plague mortality has been rapid. From 2,086 deaths in 1896 the number rose to 46,914 in the following year, and now to 86,191 in the year under review. The amount of work which fell to the share of the Port Health Officer of Bombay was enormous. No fewer than 71,498 vessels of all sorts, with 1,207,571 crew and passengers, were examined during the year. The total number of plague cases detected during 1898 was 118. Among other difficulties Major Crimmin had to contend against in carrying out his work, was the objection raised by the natives to their temperature being taken by placing a clinical thermometer in their mouths. "Every possible precaution had been taken to

remove sanitary or sentimental objections. The thermometers were washed in carbolic acid lotion and afterwards in a stream of water from a tap. Each caste had its own set of thermometers, and temperatures were taken by one of their own caste people; but the system had to be abandoned owing to caste prejudices."

9. The Sanitary Board puts the position very clearly as regards the progress of *sanitary works*. "Owing to the expenditure incurred by municipalities in connection with the plague, and to their reduced incomes from the restriction of trade due to the plague, almost every municipality has shelved the consideration of all important sanitary works." The report of the Board is brief and very much to the purpose. No circumlocution is used in bringing to notice municipal shortcomings, but unless the Board is intrusted with executive as well as consultative powers, its criticisms and recommendations will continue to have, as heretofore, little immediate result.

10. *Summary.*—The year in its main meteorological features was somewhat like its predecessor. The rainfall was up to the average and fairly well distributed. Prices of food grains were greatly lower than in the previous year. This fall in the prices of food grains was followed by a marked improvement in the public health. The prevalence of plague alone kept the year from being one of the healthiest on record. The death-rate fell from 39·84 in the previous year to 29·16. The birth-rate, being much influenced by antecedent conditions, was abnormally low during the first half of the year; during the last five months, on the other hand, in response to the return of better times towards the end of the preceding year, and in the earlier months of 1898, the birth-rate shows a very decided increase over the rate for the corresponding months of the previous year. The record of births followed the same course in the other provinces simultaneously affected by famine. The disturbing influence of famines and destructive epidemics on the relation which the birth-rate of a country ordinarily bears to its death-rate is well exemplified in the statistics of the Bombay Presidency during the year under report. Cholera, small-pox, and fevers were all of them less fatal than usual. There were only 4,368 deaths credited to cholera during the year. The small-pox deaths numbered 1,834, giving a death-rate of 0·1. The protective influence of vaccination, efficiently carried out, is well exemplified by the record of small-pox mortality for many years past in the Bombay Presidency. Unfortunately, stress of work in connection with plague prevalence and prevention necessitated the withdrawal from their proper duties of Deputy Sanitary Commissioners and other officials of the Vaccination Department, with only the result that was to be anticipated. There has been a serious decrease in the amount of vaccination work during the year. Both human and calf lymph continue to be used in the Bombay Presidency, the former still in by far the greater proportion. Fever deaths in the return include also those from plague. Of these latter there were 86,191 spread over every Registration District. The only two collectorates in the entire Presidency which have returned no deaths from plague are in Sind. The expenditure incurred owing to the prevalence or apprehension of plague has brought the finances of municipal bodies to a low ebb. The prosecution of important sanitary works will have to await the return of more prosperous times.

29th May, 1900.

No. 12.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner for the Hyderabad Assigned Districts for 1898.

The year under report was exceptionally healthy, contrasting strongly with its predecessor, which, with the single exception of the famine year of 1878, showed the highest death-rate on record. The acute distress from which the people had suffered until towards the end of 1897 was followed by a season of prosperity and rapid restoration of the public health. To this restoration the fall in price of food, the absence of epidemics, and favourable climatic conditions mainly contributed. The table on page 9 of the Report shows *jowari*, the staple food-grain of the people, to have fallen to less than half the price which ruled in the previous famine year. The year was colder and the rainfall less than in 1897. No doubt also the privations and hard times which preceded the year under review had weeded out from the population many of the diseased and the feeble, leaving the survivors with a higher average expectation of life.

2. The *birth-rate* being influenced largely by antecedent conditions was, in accordance with what might have been anticipated, a low one. From 39·7 *per mille* of population in the unhealthy year 1897 it fell to 31·3, the lowest recorded since 1873, or since the registration of vital statistics can safely be trusted. Unfortunately, although a return is given showing the death-rates for each month of the year, there is no corresponding return of the birth-rates; but if the birth-rate in Berar followed the same course as it followed in other provinces afflicted by famine in the preceding year, it would be found that, whilst the first six or seven months of 1898 recorded rates below those recorded during the corresponding months of 1897, the last five or six months recorded, on the contrary, higher rates than did the last five or six months of 1897. The lower birth-rates of the first half of the year would be influenced by the conditions of distress which prevailed in the previous year until the gathering in of the abundant autumn crops brought back better times; the increased birth-rates of the last months of 1898 would correspond with the cessation of distress and return of prosperity after the autumn-crops of 1897 had been reaped. But without the actual monthly birth returns, the course which the birth-rate followed during the year can only be inferred from the course which it is known to have followed in other provinces under more or less similar conditions.

3. The *death-rate* was the lowest recorded for any of the last 17 years. During the years prior to 1880, the Sanitary Commissioner thinks vital statistics were too imperfectly recorded to admit of their being used for comparison with those of later years. The mortality from all the principal diseases, excepting small-pox, shows a very marked decrease in the year under review as compared with the mortality of 1897. In the case of small-pox the death-rate was the same in both years. The Sanitary Commissioner thinks that the improvement of the public health in Berar consequent on the disappearance of famine and the return of prosperity was not the sole cause of the striking reduction in the mortality of the year. "Probably the starving immigrants who flocked to Berar without let or hindrance to partake of its hospitality contributed a large number of deaths in 1897, which served to raise the death-rate of that year; that their departure after the distress ceased served to lower the death-rate in 1898." In this way conditions not inherent in a tract of country, but introduced from outside, might produce an increase or decrease in its birth and death rates which, without explanation, might lead to the formation of erroneous conclusions regarding the health of its population. An example of such extraneous influence on the vital statistics of a district was given in the Sanitary Commissioner's report for the previous year. In that report he states that the explanation of the high death-rate in Amraoti was to be found in the situation of that district with regard to the neighbouring Central Provinces. From the latter the starving poor flooded the Amraoti district, seeking for work and food. Numbers of them died from the effects of chronic starvation, from which they suffered before reaching Berar, with the result of unduly raising the death-rate. The contrast between the health of the year under report and its predecessor is well shown in the infantile mortality recorded for each of the two years. In 1897, of children under one year of age there died 378·4 of every 1,000 of that age living; in the year under report the number was 181·8, or less than half.

4. Registration of vital statistics in the Province of Berar continues to receive much attention. Every available check, the Sanitary Commissioner states, is employed to improve registration. In the Resident's review of the Sanitary Report it is pointed out that the number of registers tested by civil surgeons during the year is far less than it ought to have been. The returns show that only 42 registers were tested by these officers in the entire Province. If the supervision of vaccination is one of the duties of the civil surgeons in Berar, as it is in other provinces, these officers, when visiting the villages in their districts for the purpose of inspecting the work of the vaccinators, must have many opportunities of testing at the same time the accuracy of the registration of births and deaths in those villages. As showing the opposite results attained by the systems of registration in force in different provinces, we read that in Berar "registers in villages are much more correctly kept than in municipal towns." In the Presidency of Madras, on the contrary, the registration of vital statistics in towns is far more complete than in rural areas. Needless to say that in India, the vastly greater proportion of the population being rural, it is more important to secure approximately accurate registration in rural areas than in towns. In Berar the total rural population numbers, according to last census, close on two and a half millions, whilst the urban population numbers only 356,000.

5. *History of Chief Diseases.*—From *cholera* there was not a single death recorded. During neither of the previous three years did the number of deaths from this disease fall below 10,000. The Sanitary Commissioner puts the question:—"Can this year's immunity be attributed to a reduced maximum and minimum temperature, a reduced humidity and rainfall, as compared with the previous year? These were the features of the year somewhat similar to those of 1873, as compared with 1872." Like the year under review, 1873 did not record a single case of cholera. The speculations of the Sanitary Commissioner are disposed of by the Resident in his review of the report as follows:—"The absence of importation of the disease, and the consequent freedom from contamination of the drinking water, are sufficient to account for the freedom of Berar from cholera in 1898."

6. From *small-pox*, 592 deaths, equal to a ratio of ·2 *per mille* of population, were recorded. In the previous year the number of deaths was somewhat higher. A single district, that of Buldana, contributed by far the greater number of the deaths, returning a death-rate of ·9 as compared with ·2 for the Province. Vaccination made satisfactory progress. The number of primary vaccine operations shows a decrease of 1,016 as compared with the number for the previous year, due, the Sanitary Commissioner is of opinion, to the decrease in the number of births during 1898; but there was an increase of 8,630 cases of revaccination over the number recorded in 1897–98. The proportion which the number of re-vaccinations bears to primary vaccinations is very high, 38,871 of the former to 94,032 of the latter. Unless vaccinators are well trained, and understand how to keep up the quality of their vaccine lymph, there is no little risk of the lymph degenerating when a high proportion of re-vaccination is performed. An experienced vaccinator would not use lymph taken from re-vaccinated subjects for the purpose of carrying on his operations, knowing that such lymph could rarely be trusted to reproduce the genuine vaccine vesicle; but new and ignorant vaccinators, and there are usually not a few of them in most provinces, may fail to distinguish between a typical and a modified vesicle, and by using lymph from the latter may lead to the deterioration of his work, and incomplete protection against small-pox. Of course, where, as in Madras, only calf lymph is used in all cases of vaccination and re-vaccination, there will be no risk such as that alluded to. The Sanitary Commissioner says:—"The vaccinators were also urged from time to time to increase re-vaccination." This may safely be done if only lymph from the calf is used by the vaccinators, but in Berar calf lymph, as we read paragraph 3 of the report, was used only so far as to start off the season's work. It must not, however, be overlooked that very great care is taken in this Province to see that re-vaccinations are not returned as "successful" unless they fulfil all the conditions needful to entitle them to be considered so. The Sanitary Commissioner personally inspected 234 cases of re-vaccination, and found of this number that "14 only were perfectly successful." Under the scrutiny to which re-vaccination is subjected in Berar, the percentage of successful cases is as low as 23·1; in the neighbouring Central Provinces the recorded percentage is 87·87. Next to the reduction of the mortality from small-pox in Berar to a lower ratio

than that reached in any other province of India, except Bengal, the best proof of the efficiency of the Department is the high percentage of children under one year of age who are annually protected. During the year under report 69,877 infants under one year of age were successfully vaccinated, against 89,414 births registered. But as 16,621 deaths of children under one year were recorded in the calendar year 1898 only 72,793 children would remain available for vaccination. Of this latter number, therefore, all except 2,906 were protected against small-pox by successful vaccination. The 2,906 would probably consist mostly of infants not in a fit state to undergo vaccination. Seeing that the 12 months of the calendar year do not all of them coincide with the 12 months of the vaccination season, the figures given are only an approximation, but probably a pretty close one, to the actual figures.

7. The decrease in mortality from *fever* and *bowel complaints* was very marked. The ratio of deaths from the former fell from 23·0 in the previous year to 11·5 in the year under report, whilst the ratio of deaths from dysentery and diarrhœa fell from 10·3 to 3·5. As regards fever, the Sanitary Commissioner writes :—"A reduced temperature, humidity, and rainfall as compared with the previous year appear to have lessened the deaths from this cause considerably"; whilst he thinks the same cause or causes that freed the Province from cholera and reduced the death-rate from fevers appear to have operated to reduce the mortality from dysentery and diarrhœa. But probably the cause which of all others did most to reduce the death-rate from bowel complaints was the cessation of the famine conditions of the previous year, and the return of more prosperous times with a more abundant and wholesome dietary.

8. Although plague approached the borders of Berar from both the Bombay and Central Provinces sides it did not succeed in obtaining an entrance. As the Commissioner writes :—"Considering how near plague approached Berar from both Khandeish and Wardha, I think that its check on our very borders may be fairly attributed to the efforts of our villagers themselves, strengthened by the assistance and guidance of the district authorities.

9. *Sanitary Works.*—During the past year there has been some decrease in the expenditure on sanitary works, chiefly under the heads of drainage and water-supply. It must tend to discourage municipalities in the prosecution of sanitary improvements in their towns to find that some of the schemes on which they have expended their resources have ended in partial failure. "More than one municipality," writes the Commissioner, "has reason to be grieviously disappointed with the results of a costly scheme of water-supply."

10. *Summary.*—The year was exceptionally healthy. The distress and privations of the previous famine year had given place to better times, under the influence of which the public health was rapidly restored. The birth-rate, owing doubtless to antecedent conditions unfavourable to health and fecundity, decreased from a ratio of 39·7 per thousand of population in the previous year to 31·3. The death-rate was the lowest recorded for 17 years, falling from 52·6 in 1897 to 23·4, or to less than half. Of cholera there was an entire absence, whilst small-pox was credited with the same death-rate of ·2 *per mille* of population as in the previous year. Vaccination made satisfactory progress. Although the number of primary operations was somewhat below the number recorded in the previous year, there was a large increase in the number of re-vaccinations. Under the rigorous scrutiny to which re-vaccination cases are subjected in Berar, the percentage of successful cases recorded was only 23·1; in the neighbouring Central Provinces the percentage was 87·87. The high percentage of children under one year of age successfully vaccinated continues to be a satisfactory feature of each season's work. Fevers and bowel complaints were much less fatal than in the previous year, the ratio of deaths ascribed to the former falling to less than half, and the ratio ascribed to the latter to about one-third. Although approaching close to the borders of Berar, plague did not obtain an entrance into the Province. There has been some decrease in the amount expended on sanitary works, chiefly under the heads of drainage and water-supply. Unfortunately, certain of the water-supply schemes carried out at much cost by municipalities have not proved so successful as had been anticipated.

No. 13.

Memorandum by the Army Sanitary Commission on the Administration Report of the Town of Calcutta for 1898–99.

The Health Officer's Report covers only 34 pages, and of these nearly a third are devoted to an elaborate account of the 142 cases of small-pox which were brought to notice during the year. On the other hand, no history of plague, or of the measures adopted with the object of preventing its entrance into the town, or of stamping it out after it had obtained an entrance, is given. It appears that, by order of the Lieutenant-Governor, the Health Officer was relieved of the supervision of the plague operations in order that he might thus be enabled to devote his entire attention to the conservancy of the town. A somewhat similar arrangement, it may be remembered, was considered to be expedient in Bombay; but in the case of the latter city the Health Officer devoted a large portion of his annual report to a history of the plague, and of the operations carried on with a view to its arrest. A Health Officer's report can hardly be considered to be complete which makes only casual mention of the disease which, more than any other, influenced the sanitary measures of the year. "It would be out of place on the present occasion," writes the Lieutenant-Governor, "to discuss the policy which has actuated the Government in dealing with the plague in Calcutta, the measures which were from time to time adopted, or the success or failure which attended them.

This will be done when the history of plague in Bengal comes under review." The attempt to separate a particular disease from all the others and to deal with its causes, prevention, and eradication as matters apart from the general conditions affecting the public health, could scarcely be expected to commend itself to a Health Officer. To begin with, the differentiation of plague, even by experts, from other diseases is not infrequently found to be a matter of great difficulty. It is only necessary to mention the close resemblance of fevers, and especially of relapsing fever, to plague. In the case of the latter disease even a bacteriological examination may be necessary before it can be distinguished from plague. As to preventive plague measures, experience appears to show that the most reliable of them are those which apply to the prevention of diseases in general, and that it is safer on the whole to trust to these than to measures which, in a country like India, can be evaded in spite of the utmost practicable vigilance.

2. The year was cooler than the average, and its rainfall, which amounted to 69·88 inches, was above the average of 66·39 inches. The bulk of the rainfall took place between the last week of June and the third week in July. The price of rice and *dhal* was below the average of the preceding five years. Common rice, the staple food of the poor, sold at Rs. 4. 6 per maund against Rs. 5. 2. 3 in 1897–98. Notwithstanding that plague made its appearance and accounted for 192 deaths, the year was an exceptionally healthy one. The death-rate was below the average, partly owing to lessened mortality from cholera and small-pox, and also, but to an uncertain extent, to the exodus of a considerable portion of the population in consequence of the plague scare.

3. The total number of *births* registered fell from 12,584 in the previous year to 9,530 in the year under report, or from a ratio per thousand of population of 18·4 to 13·9. The birth-rate of Calcutta, always low, owing chiefly to the small proportion of females, there being only 100 females to every 174 Hindu and 197 Mussalman males, was exceptionally low in 1898, owing to the exodus following the plague scare. An additional cause of the decrease in the number of births is the custom among women of leaving the town and proceeding to their houses in the country to give birth to their children, a custom which, as stated in the Government review of the report, was of course greatly strengthened by fear of plague. The number of still-births recorded was 720, or 7·5 to every 100 live births, and not to every 1,000 as stated, probably from oversight, in the report. This proportion is more than three times that recorded in Madras, but only half the proportion in Bombay. In the former, it is said that a considerable number of still-births remain unrecorded, and in the latter, it is believed that if all the live births were recorded, the ratio of still to live births would sensibly diminish.

4. The *death-rate* decreased from an average of 34·80 for the previous five years to 29·8 in the year under review, and was the lowest since 1893. The year was a healthy one, the price of food was below the average, and there was less mortality from cholera, small-pox, and fever; whilst the temporary diminution of the population consequent on the exodus due to the plague panic, or to the measures considered necessary for combating plague, combined with the other causes to reduce the death-rate of the year below the average of the previous five-year period. The infantile death-rate, always an unfavourable feature of the vital statistics of Calcutta, was below the average, owing partly, no doubt, to the exodus already mentioned, but was still very high. Amongst Mohamadans it reached the enormous ratio of 634·5 to every 1,000 births. For urban and suburban Calcutta combined, it was 368·5 of children under one year of age, as compared with 437·5, the mean of the previous five years.

5. *Chief Diseases.*—The recorded mortality from fever was less than it has been since 1889. This decrease the Health Officer considers to be satisfactory, and were it an actual instead of only an apparent decrease there would, no doubt, be ground for such satisfaction. But it is evident that the same influence was at work in Calcutta which in Madras and Bombay caused the decrease of the number of deaths recorded under the head of "fever" by their transfer to the head of other causes." In the words of the Health Officer:—"The returns of deaths from fevers in 1898 were lower than they should have been, as after the appearance of plague many people registered deaths under 'other causes' which would in other years have been registered under fevers." A reference to the statement on page 34 of the report seems to lend support to this conclusion. In 1898 the number of deaths therein attributed to fever fell from a mean of 8,426 to 6,060; at the same time the number of deaths recorded under the head of "other causes" rose from a mean of 8,312 to 10,267. The reduction in the number of fever deaths was thus to a large extent balanced by a corresponding increase in the number of deaths ascribed to "other causes." Believing that there is now sufficient ground for basing practical measures on the discoveries of Dr. Ross in connection with the part which that officer ascribes to the mosquito in the causation of malarial fever, the Health Officer hopes shortly to submit proposals for the employment of a few men in the extermination of mosquitoes in their breeding grounds. The proposed experiment will be watched with much interest.

6. *Cholera* was less fatal than in any year since 1889, the year in which the town and suburbs of Calcutta were amalgamated. The total number of deaths credited to this disease was only 605, against an average of 2,181 for the period 1889–97. And even from this number should be deducted 101 cases imported from beyond the limits of Calcutta, leaving 504 fatal indigenous cases. The causes of the attacks do not appear to have been determined with more precision than usual. For example, in describing the particulars of a local outbreak in the Sabjibagan busti, limited to four attacks, the Health Officers writes:—"The first was a girl of 12 years of the Bagdi caste, who was attacked on the 4th and died on the 6th February. No special cause was traced in her case. She contaminated a tank in the busti, and three other cases followed." One would like to know some particulars regarding the mode of contamination of the tank by the girl, and of how this contamination led to three, and only to three, attacks in what was doubtless, being a busti, a crowded neighbourhood. From what follows, it would appear that water is not regarded as the only medium by means of which the disease infection may be introduced into the human body. Describing the case of a coolie who was attacked on the 14th April and died the same day, the Health Officer says:—"The

attack was associated with the consumption of rotten sweetmeats obtained by begging from shopkeepers on the Bengali New Year's Day." Again, in another case :—"The cause of attack would seem to have been polluted drinking water supplied by a Bhisti in his skin bag in which he had been carrying tank water for watering roads. This patient contaminated a foul tank which directly communicated with another, and thus two more cases took place close to those tanks." Statements of the nature of those quoted are too inexact, it is feared, materially to advance our knowledge of the causation of cholera.

7. *Small-pox* was present in Calcutta during all the months of the year except October, but the total number of deaths attributed to the disease was only 85. Of the 142 attacks 59·4 per cent. proved fatal. Of the 142 cases, 33, or 26·7 per cent., had been vaccinated, and the mortality amongst the latter is stated to have been 44·9 per cent. Possibly the explanation of this enormous proportion of deaths to attacks may be that only a portion of the total number of the vaccinated who were attacked by small-pox came to notice, and that these were mostly confined to the gravest cases. The same explanation might, perhaps, apply to the record of 63·6 per cent. of deaths to attacks amongst the unvaccinated. Some support would seem to be given to such a hypothesis by a remark made to the effect that, in one quarter of the town at least, the search for persons suffering from small-pox "met with much resistance from the residents." The concealment of the slighter cases would, perhaps, be more successful than that of serious or moribund cases. The difficulty of stamping out the disease was increased during the year under report by the plague scare. The people, suspecting the vaccinators to be somehow connected with plague inoculation, assumed a hostile attitude to, and even assaulted, some of them, with the result that all vaccination work was stopped, by order, for three months. Chiefly as a consequence of the plague scare which led to this temporary suspension of vaccination, and to the exodus of a large proportion of the residents from the town, there was a decrease in the number of primary vaccinations in the year under review as compared with the number in the previous year. Primary vaccinations fell from 13,297 to 11,569, and revaccinations from 8,323 to 1,686, thus showing a decrease of 1,728 of the former and 6,637 of the latter. The large decrease in revaccinations is ascribed to the absence of the stimulus which a small-pox epidemic gives to revaccination. As already stated, small-pox caused only 85 deaths during the year. The percentage of success in primary vaccination, excluding unknown cases, was 99·07, as compared with 97·59 in the previous year. Of the 1,686 revaccinations, excluding unknown cases, 23·68 per cent. were successful, against 16·51 in the previous year. The contrast between the percentage of success in revaccination recorded in Calcutta, 23·68, and that recorded in Madras, 83·18, is very remarkable. In addition to the 13,255 primary operations and revaccinations combined, there were 158 of the former and 2,190 of the latter performed by Government officers of the Animal Vaccination Department, Calcutta, in private European houses and in public institutions, not included in the returns of the Vaccination Department of the Corporation. It seems a pity that all of the vaccine operations performed in Calcutta could not be included in the same return. Of infants under one year of age, only 3,198 were vaccinated; but those vaccinated between the ages of one and six years numbered 8,025. Although the Compulsory Vaccination Act is in force in Calcutta, it does not compel the people to have their children vaccinated before they have completed one year of age. The consequence of this rule is seen in the small-pox mortality returns for the year. Of 85 deaths recorded, 13 were those of children under one year of age. The state of vaccination in Calcutta is, in the opinion of the Health Officer, "very bad"; and he has submitted a scheme for the reorganisation of the Department. One of the chief features of this scheme is the appointment of a more highly trained and better paid class of vaccinators. "Our vaccinators," writes the Health Officer, "receive the pay of coolies, and are not proper persons to decide whether children are in a fit state for vaccination, and the other responsible duties of their office." The scheme has received sanction since the close of the year. Summonses were issued under the Vaccination Act in 408 cases, but only 48 cases had ultimately to be heard in court, with the result that in 44 cases the offenders were fined, and in two warned and discharged, while two cases were pending at the end of the year.

8. *Sanitary Works.*—The apprehension and presence of plague have given an impetus to sanitary improvement. One of the chief defects in Calcutta is the site-crowding, which from year to year was pressed on the notice of the municipality by the former Health Officer, Dr Simpson. The present Health Officer, dealing with the question, writes :—"Anyone experienced in sanitary matters can see that nothing approaching an average standard of sanitation can be attained without to a considerable extent demolishing and reconstructing the town." Timely interposition on the part of the authorities might have prevented much of this site-crowding, and so have saved a vast expenditure of money which will be required to remedy it. The filling up and improvement of tanks continues to be carried on from year to year. The Health Officer in describing the state of the cow byres says they are badly constructed, ill-drained, and over-crowded. "The results of analysis show that most of the milk sold in Calcutta is adulterated with water to the extent of from 10 to 75 per cent." Thirty per cent. may be taken as a fair average of added water. Facts of this nature may help to throw light on the causes of the enormously high infantile death-rate annually recorded in Calcutta. Of the cow-keeper who habitually adulterates the milk he sells, the Health Officer writes :—"It would be interesting to know how many infant lives this simple-minded felon accounts for on the average in a year. Fortunately for the infants the native mother has generally a proper sense of the duties of maternity and nurses her child."

9. *Summary.*—Notwithstanding plague, which accounted for 192 deaths, the year was exceptionally healthy. The price of food was below the average. There was no destructive epidemic. Cholera was less fatal than in any year since 1889, and small-pox had attributed to it only 85 deaths. The mortality credited to fever was less than the average for the previous five-year period; but there are grounds for believing that this decrease is largely counterbalanced by an increase in the number of deaths recorded under the head of "other causes." The plague panic led to the registration of many deaths as due to "other causes" which were in reality due to fever. Vaccination work suffered much from a suspicion which got abroad amongst the people that it was somehow connected with plague

inoculation. As a consequence of the spread of this suspicion, people not only refused to have their children vaccinated but in some instances assaulted the vaccinators. For nearly three months during which this hostile attitude of the inhabitants towards vaccination continued, vaccine operations were stopped by order of the Chairman of the Corporation. There was a decrease in the number of primary vaccine operations, but the percentage of successful cases rose from 97·59 to 99·07. Of revaccination there was a large decrease, due, the Health Officer thinks, in main part to the absence of the stimulus which small-pox in severe epidemic form gives to vaccination. A scheme has been proposed by the Health Officer for the reorganisation of the Vaccination Department. One of the most important features of this scheme is a proposal to improve the training and increase the pay of the vaccinators. Sanitation in Calcutta has naturally received an impetus from apprehensions and presence of plague. The site-crowding, which has been permitted to grow up and become a notorious feature of the town, is one of the chief sanitary evils which have to be grappled with : the application of an effectual remedy will be a big and costly undertaking.

No. 14.

Memorandum by the Army Sanitary Commission on the Administration Report of the Madras Municipality for 1898–99.

According to the table on page 41 of the report, the rainfall recorded for the calendar year 1898 was 68·14 inches. It was below the average in January and from March until July, and above the average in the other months. The excess for the whole year was 19·12 inches. The fall between the 15th of October and the end of the year was 43 inches as compared with 9½ in the previous year, and with an average of 26 inches. The temperature was below the average in January, March, September, and October, normal in November, and above the average during the other months. The prices of the staple food grains, second quality rice and *ragi* ruled much above normal for the whole year, with a slight tendency to fall in December. But even during the latter month a rupee, which ordinarily would buy 12·1 seers of rice, or 24·8 of *ragi*, bought only 10·3 of the former and 16·4 of the latter. Thus, 1897, with a greatly lower rainfall between the middle of October and the close of the year, together with cheaper food, recorded 2,616 more births than deaths, whilst 1898 with a vastly greater rainfall during its last two-and-a-half months, and with higher prices of food, recorded 1,592 more deaths than births. Without claiming that the difference in the vital statistics of the two years is exactly reflected in the difference of their food prices and climatic conditions, there can be little question that the former were largely influenced, as they usually are, by the latter.

2 An examination of the statement of *births* at page 30 of the report shows that the ratios were, excepting in June, lower during the first seven months of the year under report than in the corresponding months of 1897 ; and that, on the other hand, the ratios for each of the last five months were so much higher in 1898 than in the previous year as to make good the deficiency in the preceding months, the total ratio of 41·3 coming out the same for both years. We have noticed that almost the same course was followed by the birth-rates of the two years in the provinces subjected to famine or abnormally high prices in 1896–97. It has to be noted, however, that whilst elsewhere there was generally a fall in the prices of food following the cessation of famine conditions and the return of prosperity, in Madras city food prices were higher in 1898 than in 1897. The total number of children born alive during the year under report was 18,694, or only eight fewer than in 1897. There were two still-births to every 100 children born alive. This is somewhat less than the proportion recorded in 1897, which was regarded by the President as unquestionably too low for a city like Madras. In the present report it is said :—"No doubt there is still considerable concealment owing to popular prejudices, and dead children are easily got rid of in this country." The popularity of lying-in hospitals appears to be peculiar to Madras : nearly three thousand births took place in these institutions during the year, according to paragraph 170 of the report. In other Indian cities public lying-in hospitals, if they exist, are comparatively little resorted to.

3. There were 20,286 *deaths* recorded, against 16,086 in the previous year, giving a ratio per thousand of population of 44·8 as compared with 35·5 in 1897. The mortality according to sex would seem to indicate a preponderance of females in the population of Madras city. Of females, 10,333 died during the year under report as against 9,953 males, or in the proportion of 100 of the former to 93 of the latter. According to paragraph 168 of the report the population of Madras city is composed of the two sexes in almost equal numbers, females exceeding males by only 884 in a total of 452,518. The contrast between these numbers and the numbers for Bombay city are remarkable. In the latter, females instead of being in excess, as in Madras, are only in the proportion of 100 to 170 males. The increase of 4,200 in the number of deaths over the number in the previous year was due to greater mortality under the head of all the principal diseases, but chiefly under the heads of cholera, dysentery, measles, and "other diseases." Ordinarily, when there is a large divergence between the number of deaths recorded in any two years, fevers take their share in bringing this about. But in each of the years 1897 and 1898 the numbers of deaths attributed to fevers were practically the same—5,484 in the former and 5,489 in the latter.

4. *Chief Diseases.*—Not since 1891 has there been so fatal an epidemic of *cholera*. The disease prevailed in sporadic form during the last three months of 1897, and in January of the year under report caused 47 deaths. From this time onwards it decreased until only one death was recorded against it in June. In the following month, however, the disease suddenly assumed an epidemic

form, causing 94 deaths and reaching its climax with 311 deaths in August. During the remaining four months it again gradually subsided until, from causing 176 deaths in September, 19 deaths only were attributed to it in December. As in most other years, the months of greatest cholera prevalence in Madras were those of August, September, and October. In the case of two houses the President considers that the disease could be traced to the use of well water. "In both instances there were latrines within the drainage area of the well." Every division of the town suffered; but the incidence of the disease was most severe in the First Division, which includes some of the most insanitary centres. Colonel Weir has noticed that in Bombay children are less liable to cholera than adults: this also has been observed to be the case in Madras city. Endeavours to isolate those attacked by cholera were not apparently more successful in Madras than elsewhere. Experience seems to show that attempts at isolation do perhaps more harm than good, by causing the people to conceal cases of the disease. As notification of cholera cases led to disinfection of the houses in which these occurred, and as disinfection was disliked by the people, medical practitioners found that, in their own interests, notification was inexpedient. The consequence was that "the instances in which notification was given were but few."

5. The total number of deaths due to *small-pox* was 116, or two more than in the previous year. This gives a ratio of ·2 *per mille* of population as compared with ·6 for the Madras Presidency as a whole. The statements given in paragraph 175 deserve attention. Of the 116 persons who died of small-pox in Madras city during the year, 50 were unvaccinated, 40 said to have been vaccinated but had no marks, whilst 26 had been vaccinated. Of 23 deaths among the vaccinated, 14 are stated to have taken place amongst children under 10 years of age, and nine amongst persons beyond 10 years. So many as 14 deaths occurring amongst children within less than 10 years of the time of their having been vaccinated out of a total of 177 vaccinated persons attacked, suggests the need for inquiry as to the genuineness of the vaccine lymph used and the qualifications of the vaccinators employed in using it. Taking two as the minimum number of vaccine marks necessary to indicate a fair amount of security against small pox, the mortality per cent., according to Marson's tabulated results, amongst persons attacked by small-pox who can show two such marks, is 4·70 per cent. With four or more marks the mortality per cent. is only 0·55. During the year 1898–99 the total number of persons vaccinated was 28,186, showing a decrease of 4,896 compared with the number for 1897–98. The recorded percentage of successful cases, at the same time, fell from 96·76 to 95·79; but this decrease "was due to the low percentage of success obtained in revaccination." The ratio of successful cases in primary vaccination was practically the same in both years: in revaccination it decreased from 86·97 to 83·18. Regarding these latter figures the remark is made in the Government review of the report:—"The percentage of success in the case of revaccinations is, however, not above suspicion, seeing that a careful investigation of the matter made by the Sanitary Commissioner has shown that the normal rate of success in revaccination must be between 75 and 60 per cent." In the Government review it is estimated that, after deducting the number of children who died under one year of age from the total number of births registered, there remained available for vaccination 12,881. The number of children under one year of age who were successfully vaccinated was 13,381; so that it might at first sight be concluded that vaccination must be very complete, seeing that the number vaccinated is in excess of the number estimated to be available for vaccination. But it is pointed out by the Government that, of the 13,381 successfully vaccinated, only 9,500 appear to have been born in Madras; "and it is stated that the 3,044 births which occurred in the hospitals were not traced by the vaccination staff for want of sufficient information. It is thus evident that more than one-fourth of the children under one year available for vaccination and born in Madras remained unprotected. This is not satisfactory, and the Government trusts that adequate steps will be taken to improve matters." Calculated on the census figures, 62·2 *per mille* of the population were vaccinated in 1898–99, a ratio far above the birth ratio, which was only 41·3. Of the total number of 28,186 cases vaccinated during 1898–99, the various inspecting agencies verified 20,586. Calf lymph is used; and that the people may have no excuse for neglecting to avail themselves of vaccination, on certain days of the week, the "calf is sent round with the vaccinators to the crowded paracherries, fishermen huts of Cassimode and Tinnivelli Settlement huts, and the unprotected are vaccinated on the spot."

6. The deaths from *fever* were practically the same in number as in the previous year. It is noted that in October the numbers registered suddenly fell. This decrease was attributed, to some extent, to the fear the public had that troublesome investigations might follow the notification of fever cases during the time that apprehensions were entertained of a plague epidemic; fever cases being regarded with suspicion by the sanitary authorities so long as the diagnosis was incomplete and there seemed any risk of their being really cases of plague.

7. Fortunately, *plague*, although 15 cases were imported up to the 31st of March, 1899, did not secure a footing in the city of Madras. Additional hospitals and segregation camps were prepared and kept in readiness for immediate occupation by plague cases. An effort was made to subject all persons to surveillance arriving in Madras by train from infected localities. The President writes:—"The system worked fairly well, but of course a certain percentage of arrivals altogether escaped observation, and could not be traced either by the sanitary staff or the police. It is good luck alone that has saved the city from indigenous cases, which might very well have followed, if one of these persons who eluded the utmost vigilance manifested had developed plague and died unknown." Like all such measures devised with the object of protecting places in direct communication by land with infected localities against importation of disease, the measures adopted at Madras are admitted to have been an incomplete safeguard against plague. The President acknowledges that however carefully and zealously put into execution "loopholes of escape are found in every part of the system depended on." Amongst other precautionary measures adopted against plague, an attempt was made to destroy the rats and mice in the city. This failed. No impression appeared to be made on the total rat population, in spite of the rewards offered for their destruction. Inoculation with Haffkine's prophylactic was commenced, and altogether 5,853 persons were operated upon.

8. *Sanitary Works.*—It is stated in the Government review of the report that:—"No substantial advance was made during the year in the sanitary condition of the city, but several important steps were taken which may be expected to effect an improvement in future." The Mylapur drainage system was, however, opened, and is said to be, on the whole, a great success. Drainage of the other quarters of the city continues to be one of the chief sanitary requirements of Madras. The President calculates that, after the disposal of 4,200,000 gallons of sewage daily on the existing farms, or by discharge into the sea, there remain of the 8,210,000 gallons of pipe water daily used 4,010,000 gallons to be soaked into the soil or evaporated. And this is an under-estimate of the soakage, as no account is taken of the additional quantity raised from wells. The removal of only half the quantity of water introduced into Madras is thus arranged for, and the removal of the remaining half is perhaps the most important consideration in connection with the improvement of the health of the town. A satisfactory feature of the mode of disposal of a portion of the town sewage is its profitable utilisation on farms. A profit of Rs. 38,300 was realised from these farms during the year under report, as compared with Rs. 33,545 in the previous year, and with only Rs. 2,851 in 1896–97. A certain number of dirty and useless wells were closed during the year, but until the present intermittent water-supply is replaced by a continuous supply, the complete disuse of well water in Madras will not be practicable. Next to efficient drainage, this question of a sufficient and pure water supply is perhaps the most important. No satisfactory remedy seems yet to have been discovered for effectually dealing with the chronic difficulty experienced in obtaining a sufficient number of scavengers. When these go on strike, as they appear to do whenever it seems good to them, the inconvenience and even danger to the public health, consequent upon the non-removal or incomplete removal of night-soil and other refuse, cannot but be serious.

9. *Summary.*—The year was one of a rainfall much above the average, and also a year of higher prices of food. The rainfall during the last two and a half months of the year measured 43 inches, as compared with only 9½ in the corresponding months of the previous year. The birth-rate, 41·3 per thousand of population, was the same as that of 1897; but the death-rate rose from 35·5 in the previous year to 44·8. All of the chief diseases contributed to this increased mortality, but those which contributed most were cholera, dysentery, measles, and "other diseases." The number of fever deaths, contrary to what might have been anticipated in view of the unusually heavy rainfall during the last months of the year, was practically the same as in the previous year. There seems to be no doubt that this result was, at least partly, brought about by the inclusion of some of the deaths caused by fever under the head of "other diseases." Not since 1891 has the mortality from cholera been so great. The number of cholera deaths recorded was 778. The actual number was probably greater, as the fear that those attacked might be taken from their homes to hospitals seems to have led to concealment of the disease. The disinfection of those houses in which cholera was reported to have occurred was disliked by the people, and no doubt also contributed to concealment of cases. There were 116 deaths from small-pox, or two more than in 1897. Of 23 deaths which occurred amongst those who had previously been vaccinated, no fewer than 14 were deaths of children under 10 years of age. This mortality among children whose vaccination must have been comparatively recent, suggests the need for inquiry as to the genuineness of the lymph used and the fitness of the vaccinators. The percentage of success claimed in revaccination fell from 86·97 to 83·18, but is still very high, unless on the supposition that the primary vaccination of the cases was imperfect. Calf lymph is used in Madras, and in certain quarters of the city the calf is taken about with the vaccinator and the people vaccinated directly from it. Only 15 cases of plague, all of them imported, occurred in Madras city during the year. Elaborate preparations were made for combating the disease, but fortunately no indigenous cases followed those imported. No substantial advance was made during the year in the sanitary condition of the city. The Mylapur drainage scheme was, however, opened, and is said to be a great success. A satisfactory feature in connection with the drainage of Madras is the profitable utilisation of a portion of the sewage on farms. The chronic difficulty experienced in obtaining a sufficiency of labour for conservancy purposes has not yet been satisfactorily overcome.

29th May, 1900.

No. 15.

Memorandum by the Army Sanitary Commission on the Administration Report of the Municipal Commissioner for the City of Bombay for the Year 1898–99.

The Report of the Health Officer of the City of Bombay carries on the history of the plague epidemic which broke out towards the end of 1896, and continued to increase in fatality during the following year, and still more during the year under review. There is little that is new in the account given of the progress of the epidemic. Commencing with a record of 1,936 deaths in 1896, it was credited in the year following with 11,003, and now in the year under report with 18,185. Colonel Weir fervently hopes that 1898 will be the last of the abnormal cycle of years. His hopes have not been fulfilled, as will be only too evident when next year's history comes to be written. Nor was the Meteorological Reporter more happy in his forecast when he expressed the opinion "that the remarkable period through which India has passed had terminated, and a period of normal conditions was probable for two or three years." Colonel Weir mentions as a curious and important fact that the ground temperatures since 1896 have been rising at all depths, more or less, except in the cold season. This rise, five feet below the surface, was from 84·8° in 1896 to 86·3° in the year under review. Possibly, the rise may be in some way connected with variations in the amount of the rainfall; it is stated in the next paragraph that "the total rainfall for 1898 was 7·44 inches less

than in 1897 and 13·56 inches less than in 1896." Amongst other curious phenomena, Colonel Weir noticed that on the morning of the 6th of July the north part of the island was pervaded by a most offensive smell, tainting the air far and wide. This effluvium, he thinks, may have been due to the decomposition of dead rats ; for, he says, a number of bodies of rats were afterwards found in the suburbs. It was likewise noticed that during the epidemic of 1898 few mosquitoes were seen, and it seemed as if they had almost disappeared from the island. The disappearance of mosquitoes was again noticed in August. Whilst describing these and other unusual phenomena observed during the year, Colonel Weir does not attempt to suggest the existence of a connection between them and the course of the plague epidemic.

2. The course of the epidemic somewhat resembled that followed by it in the previous year. The rise in mortality which began in the middle of December, 1897, continued until, on the 9th of February, the plague deaths numbered 347. From the latter date, the level of mortality, although fluctuating, remained high until it attained its maximum in the middle of March, after which it rapidly fell until it reached its lowest point in June. Although it again irregularly rose until it reached a second climax in October, its fatality did not, until the end of the year, at all approximate that recorded in February and March. At the end of the year, the mortality curve was, however, again upwards. The diagram facing page 703 of the report admirably illustrates the course followed by plague throughout the year as compared with its course in 1897.

3. The measures adopted with the object of preventing the extension and lessening the fatality of the epidemic in Bombay, the Health Officer believes, have been successful in saving many lives ; but he confesses that "after three years of incessant activity against plague, the disease is more virulent and destructive in type than ever." At the same time, the returns show that in spite of the measures taken to prevent its extension, plague has effected an entrance into nearly every collectorate of the Presidency. The great danger in enforcing plague measures, Colonel Weir thinks, is that they may, if unpopular, excite general opposition and lead to concealment. Selecting, by way of example, a single day during the year, he estimates that on this day there were, out of a total of 264 deaths from all causes, 184 from plague. Of these 184, only 68 had occurred in hospitals ; the balance, 116, had therefore been concealed. No wonder that with such results the Health Officer was led to recommend "the abandonment of contact segregation, because it could not be carried out, however excellent in principle." The opening up of the houses by the removal of tiles from their roofs, the destruction of rats, the flushing with disinfectants of the buildings in which cases had occurred, the encouragement of inoculation against plague, as vaccination is used against small-pox, were the chief measures persevered with during the year 1898. Colonel Weir has to admit, however, that "the experience of this year indicates that the measures enforced in 1898 did not produce better results than the measures adopted in the previous year." Those who have faith in quarantine measures will be disappointed to learn from an officer who has seen more of plague than probably anyone living, that :—"Not a single restrictive measure on the movements of the population either stayed or even perceptibly influenced the epidemic" in Bombay.

4. The sanitary improvement of Bombay has naturally received a strong stimulus from the plague visitation. Much has been and is being done towards the completion of the drainage system of the city, but an immense amount of work still remains unfinished ; "for nearly one quarter of the area of the island has to be drained, and buildings by whole localities have yet to be drained and connected with sewers." A very important work, the removal of refuse outside the island of Bombay, has commenced. The question of overcrowding is one of the most difficult the authorities have to deal with. Colonel Weir seems to think the prevention of overcrowding to be well-nigh hopeless. He asks :—"Is there a single employer of labour in Bombay from the private individual to the master of a few servants, from the Municipalities to the Port Trustees, from the Port Trustees to any higher authority who is able to prevent over-crowding amongst their own servants"? Regarding the provision of proper houses for the poor, 100,000, or more, of whom now sleep on the damp ground, he adds :—"Take the most sanitary buildings in Bombay and allow the poor class to enter it, and in a few weeks they will make it as insanitary as the most insanitary chawl in the most insanitary area."

5. Anti-plague inoculation made some progress during the year. The total number of persons inoculated was 27,887. The degree of protection which inoculation affords against attack, and the extent to which it reduces the risk of a fatal result in case of attack, may not be known with precision, any more than the period of time during which it confers more or less immunity from attack ; yet the experience of those who have practised inoculation, supported by the opinion of the Plague Commission, favours the belief that, carried out under proper conditions, it exercises a powerful controlling influence over the disease. Still, if a previous attack of plague fails to confer complete protection against a second attack, it is scarcely probable that inoculation would be more successful. In paragraph 92 of his report, Colonel Weir describes a case which came under his own observation. The patient was inoculated in February : six months afterwards he suffered from plague, but recovered after having been two months in hospital. In November he had a second attack of plague and died in three or four days. In this case, which is surely most exceptional, neither inoculation nor an attack of plague, nor both together, prevented a second attack with a speedily fatal result. Surprise is expressed that a greater number of Europeans and Eurasians did not submit themselves to be inoculated ; but it is explained that these classes, living under the favourable hygienic conditions which surround them, think the risk of contracting plague so slight as scarcely to be worth the trouble of taking special means of protection against it. Observation seems to show that susceptibility to attack is less under than over five years of age, and that persons between 25 and 40 years are the most susceptible. The experience of another year confirms what was previously observed regarding the influence of ventilation in modifying plague mortality. "The mortality decreased with the height of the dwelling, being nearly 86 on the ground floor, over 77 on the first floor, 71 on the second floor, 61 on the third floor, 57 on the fourth floor, and 51 on the fifth floor."

6. Of the total number of 51,916 deaths in Bombay during the year, giving a ratio of mortality per thousand of population of 63·23, plague was of itself accountable for 18,185, or a ratio of 22·12. Both *cholera* and *small-pox* were in comparative abeyance, the former having attributed to it a death-rate of only ·12 and the latter of only ·06 per thousand. Nothwithstanding the unceasing combat with plague throughout the year, no interruption of the efficient working of the Vaccination Department was permitted. Last year the number of children successfully vaccinated under one year of age was 9,765; in the year under report the number was 9,050. In addition, 2,397 children under six years were vaccinated, and 150 persons who were upwards of that age. These figures show no great falling-off as compared with those of the previous year. Of re-vaccinations there were 1,062, of which only 230 were ascertained to be successful, 670 remaining "unknown." The number of live-births recorded during the year was 10,784. The mortality amongst children under one year of age was enormous. In the table at page 826 of the Report no fewer than 6,279 deaths of children under one year of age, exclusive of still-births, are recorded out of a total of only 10,784 live-births. Deducting the former from the latter figures, only 4,505 would remain available for vaccination; and of these a considerable number would probably, from various causes, be unfit to undergo vaccination. Such figures may well raise doubts as to the completeness of the registration of births. The proportion of still-births to children born alive continues, as heretofore, to be very high in Bombay; there were 1,569 of the former to 10,784 of the latter. If these figures can be relied upon it is striking to find that, in a city with a population, according to last census, of 821,704 inhabitants, there were only 10,784 children born alive, and that of this number 6,279 died within the year, leaving a residue of only 4,505 survivors. The plague epidemic is responsible, as Colonel Weir points out, for much that is abnormal in the birth and death rates.

7. The remaining chief causes of mortality during the year were *diseases of the respiratory system*, *phthisis*, and *fever*. The first of these are credited with 8,423 deaths, or 2,885 above the average. The excess suggests the record of a certain number of plague deaths under the head of respiratory diseases. Phthisis continues to be very fatal, 5,624 deaths having been attributed to it. The causes to which this great mortality is due in Bombay have been dealt with in former reports. They resolve themselves chiefly into bad ventilation and overcrowding. The causes suggest the remedy. The victims are, to a disproportionate degree, females, and especially those of the castes most prone to the seclusion of their women, Mussalmans and some high-caste Hindus. Compared with the mortality from phthisis in 1897, there was a decrease of 303 deaths, which Colonel Weir thinks "indicates one of two things, *i.e.*, either that there had not been great concealment of plague, or that the phthisical population had been reduced by plague." The mortality from fever was much less than in the previous year. To *enteric fever* 37 deaths were referred, being four more than in 1897 and seven more than the average. So small a number in a population of upwards of eight hundred thousand contrasts strikingly with the heavy mortality from the same disease among Europeans in India, notwithstanding the better sanitary environment of the latter. From *relapsing fever* 546 deaths were recorded; the disease had two periods of greatest prevalence, one occurring in March and the other in October. It will be seen that those two periods coincide with the two periods of maximum mortality from plague during the year. It was not always easy, even with a bacteriological examination, to differentiate the two diseases. During the previous year there was a serious increase in the fever mortality concurrently with the prevalence of cholera. In Madras the Sanitary Commissioner found, under similar conditions of cholera prevalence, that many deaths caused by cholera were registered under the head of "fever." Taking the whole year 1898, Colonel Weir observes that, although the mortality from fever rose and fell to some extent synchronously with the increase and decrease of plague mortality, this concurrent movement of the two diseases was less marked than it was in the previous year. The investigations of Ross, the Health Officer remarks, "suggest the necessity of studying the mosquito life of this island."

8. *Summary.*—The report is mainly a continuation of the history of the plague in the City of Bombay. In spite of the determined efforts to restrict its spread, cases of the disease were reported during the year from almost every collectorate in the Presidency. As the Health Officer puts it:—"After three years of incessant activity against plague, the disease is more virulent and destructive in type than ever." The number of deaths due to it in Bombay City increased from 11,003 in 1897 to 18,185 in the year under review. Concealment of cases continued to be one of the chief difficulties encountered in dealing with the epidemic. The Health Officer has recommended the abandonment of contact segregration, because it could not be carried out, however excellent in principle. Improving ventilation of houses by removing tiles from their roofs, flushing with disinfectants buildings in which cases of the diseases had been known to occur, and inoculation with anti-plague serum, were some of the measures on which reliance was placed in the combat with plague. The other chief diseases were not unusually prevalent. Cholera is credited with a death-rate of only ·12 *per mille* of population, and small-pox of ·06. The progress of vaccination was not interrupted by the campaign carried on against plague. The number of successful primary vaccinations fell but little short of the number in the previous year. The mortality from respiratory diseases rose to such a height as to suggest the record of cases of plague under this head. Phthisis, as usual, was very fatal, more especially amongst Mussalmans and some high-caste Hindus, classes of the population given to keeping their women secluded. The number of fever deaths rose and fell to some extent in sympathy with the rise and fall in plague prevalence, but to a less degree than in 1897. The differentiation of cases of relapsing fever from plague was sometimes difficult even with the aid of a bacteriological examination. Under the stimulus of the plague epidemic, sanitary measures in Bombay City were vigorously prosecuted. The drainage scheme is being actively proceeded with; but a vast amount of work remains to be finished before the scheme can be brought to completion.

SALE OF GOVERNMENT PUBLICATIONS.

The under-mentioned Firms have been appointed sole Agents for the sale of Government Publications including Parliamentary Reports and Papers, Acts of Parliament, Record Office Publications, &c., &c., and all such works can be purchased from them either directly or through retail booksellers, who are entitled to a discount of 25 per cent. from the selling prices :—

IN ENGLAND :—

For all publications *excepting* Ordnance and Geological Maps, the Hydrographical Works of the Admiralty, and Patent Office Publications :—MESSRS. EYRE AND SPOTTISWOODE, East Harding Street, E.C.

For Hydrographical Works of the Admiralty :—Mr. J. D. POTTER, 145, Minories, E.C.

Patent Office Publications are sold at the Patent Office.

For all publications *excepting* the Hydrographical Works of the Admiralty, Patent Office Publications, and Ordnance and Geological Maps.

IN SCOTLAND :—MESSRS. OLIVER AND BOYD, Edinburgh.

IN IRELAND :—MR. E. PONSONBY, 116, Grafton Street, Dublin.

ORDNANCE SURVEY MAPS OF GREAT BRITAIN AND IRELAND :—There are Agents for the sale of these Maps in most of the chief towns. Copies can also be ordered at many Head Post Offices, and through any Bookseller, or from the Director-General Ordnance Survey, Southampton ; or, in the case of Ireland, from the Officer in Charge Ordnance Survey, Dublin.

GEOLOGICAL SURVEY PUBLICATIONS OF GREAT BRITAIN AND IRELAND :—The Agents for the sale of Ordnance Survey Maps are also, as a rule, agents for the sale of Geological Publications.

The following is a list of some of the more important Parliamentary and Official Publications recently issued :—

Parliamentary:

Statutes—

Public General, Session 1900, Sess. 2, and 1901. With Index, Tables, &c. Roy. 8vo. Cloth. Price 3*s.*

Second Revised Edition. A.D. 1235–1713 to A.D. 1872–1883. XVI. Vols. Price 7*s.* 6*d.* each.

Revised Editions. Tables showing subsequent Repeals, effected by Acts of 63 & 64 Vict. 1900. Price 6*d.*

Statutes in Force. Chronological Table of and Index to. 17th Edition. To end of 1 Edward VII. (1901). 2 vols. Price 10*s.* 6*d.*

The Statutory Rules and Orders revised. Statutory Rules and Orders, other than those of a local, personal, or temporary character, issued prior to 1890, and now in force. Vols. I. to VIII. Price 10*s.* each.

Statutory Rules and Orders other than those of a Local, Personal, or Temporary Character. With a List of the more important Statutory Orders of a Local Character arranged in classes ; and an Index. Roy. 8vo. Boards. Issued in the years 1890, 1891, 1892, 1893, 1894, 1895, 1896, 1897, 1898, 1899, and 1900. Price 10*s.* each.

Statutory Rules and Orders in force on 31st December 1899. Index to. Price 10*s.*

Statutory Rules and Orders, 1901. Registered under the Rules Publication Act, 1893. In course of issue.

Index to Local and Personal Acts, 1801–1899. Price 10*s.*

Acts of Parliament, Local and Private, Session 1901. In course of issue.

[Cd. 416.] EDUCATIONAL SUBJECTS. Special Reports. Vol. IV. Canada, Newfoundland, &c. Price 4*s.* 6*d.*

[Cd. 417.] Do. Vol. V. Cape Colony, Australia, &c. Price 4*s.*

[Cd. 418.] Do. Vol. VI. Preparatory Schools for Boys. Price 2*s.* 3½*d.*

[Cd. 419.] TECHNICAL AND COMMERCIAL EDUCATION in East Prussia, Poland, Galicia, &c., James Baker, F.R.G.S. Price 6*d.*

[Cd. 638.] LOCAL TAXATION. ROYAL COMMISSION. Final Report as to England and Wales. Price 1*s.* 6*d.*

[Cd. 668.] FACTORIES AND WORKSHOPS. Report of Chief Inspector Year 1900. Price 6*s.* 4*d.*

[Cd. 692.] ARSENICAL POISONING (FOOD, BEER, AND OTHER DRINKS). First Report of Royal Commrs. Pt. I. Price 2*d.*

[Cd. 726.] FISHING BOARD FOR SCOTLAND. Report on Scientific Investigations. Year 1900. Price 4*s.* 9*d.*

[Cd. 779.] PROPOSED NEW GERMAN TARIFF. Translation. Part I. Price 4½*d.*

[Cd. 818.] MINES AND QUARRIES. General Report and Statistics of Output, 1900. Price 1*s.* 4½*d.*

[Cd. 827.] EAST INDIA. Review of Trade, 1900-1. Price 4*d.*

MINES. Reports of H.M. Inspectors for 1900, with Summaries of the Statistical portion under the provisions of the Coal Mines Regulation Act, 1887 ; Metalliferous Mines Regulation Acts, 1872–1875 ; Slate Mines (Gunpowder) Act, 1882, Districts Nos. 1 to 13. (Complete.) Price 9*s.* 2½*d.*

MINES in the United Kingdom and the Isle of Man. List of, for 1900. Price 3*s.*

QUARRIES. Do. do. do. 1900. Price 4*s.* 6*d.*

MINES ABANDONED. List of the Plans of. Corrected to 31st December 1900. Price 1*s.*

ACCIDENTS AT DOCKS, WHARVES, AND QUAYS. Report upon. Price 6*d.*

The following appear periodically, and can be subscribed for :—

TRADE OF THE UNITED KINGDOM WITH BRITISH POSSESSIONS AND FOREIGN COUNTRIES, showing the Quantities and the Declared Value of the Articles.

TRADE REPORTS of the British Colonies, with information relative to population and general condition.

TRADE REPORTS by His Majesty's Representatives in Foreign Countries, and Reports on Commercial and General Interests.

The Proceedings of Parliament in public and private business, published daily. House of Lords, Price 1*d* per 4 pp. ; House of Commons, 1*d.* per 8 pp.

A. GODLEY,
Under Secretary of State for India.

INDIA OFFICE,
November, 1901.

REPORT.

The present Report on Sanitary Measures in India during the year 1899 is prepared for presentation to Parliament. It contains chapters on the health of the European and Native troops, on the health of prisoners in jails, and on the health of the general population; it also contains chapters on vaccination, on medical institutions, including medical schools and lunatic asylums, and a chapter on sanitary works. Appended to the Report are abstracts of reports by the three principal Sanitary Commissioners in India, and memoranda by the Army Sanitary Commission in England reviewing the several Sanitary Reports for India.

I.—EUROPEAN ARMY.

Sickness and mortality in 1899.

The health of the European troops on service in India in 1899 was much more satisfactory than in the previous year. On an average strength of 67,697, the admissions into hospital were in the ratio of 1,149 per 1,000, against 1,437 in 1898, the daily sick-rate fell from 90 to 73, and the death-rate from 20·05 to 12·75. The invaliding ratio (32) was lower by 6 per 1,000, so that the total loss by death and invaliding was equal to 44 per 1,000, a decrease of 14 per 1,000 on the previous year.

The Presidential Army system was abolished in 1894, and the whole of the force in India is now designated the Army of India, divided into the Bengal, Punjab, Madras, and Bombay Commands. This organization took effect from the 1st April 1897.

The following statement shows the relative extent of sickness and mortality among European troops in the four Commands during 1899 and the previous year :—

Commands.		Average Strength.	Ratio per 1,000 of Average Strength.				
			Admissions.	Daily Sick.	Deaths.	Invaliding.	Total Loss.
Bengal	1898	20,060	1,184	96	19·54	44	64
	1899	21,278	1,191	81	13·82	36	50
Punjab	1898	18,388	1,558	90	27·63	40	68
	1899	18,080	1,085	62	14·82	24	39
Madras	1898	12,337	1,293	89	8·59	44	53
	1899	12,876	1,259	82	10·10	39	49
Bombay ...	1898	14,612	1,420	86	18·20	29	47
	1899	15,462	1,073	67	11·06	29	40
INDIA ...	1898	67,741	1,437	90	20·05	38	58
	1899	67,697	1,149	73	12·75	32	44

It will be seen from the above statement that in all the Commands, except that of Madras, there was a marked improvement in the health of the troops as compared with the previous year. In regard to mortality the improvement was greatest in the Punjab Command, its death-rate having fallen by nearly 13 per 1,000.

The chief causes of sickness in the whole European Army were, as in the year 1898, ague and venereal diseases, the former yielding a ratio of 235 per 1,000 against 394 in 1898, and the latter 313 per 1,000 against 363. Nearly a half (47 per cent.) of the total sickness resulted from these two causes. Enteric fever, as usual, was the chief cause of mortality, but the death-rate from it was only 5·14 per 1,000 against 10·17 in 1898. Over 40 per cent. of the total deaths were due to this cause.

Groups of stations.—The following table shows the sickness and mortality among the European troops according to groups :—

Groups.	Average Strength.	Ratio per 1,000 of Average Strength.		
		Admissions.	Daily Sick.	Deaths.
Burma Coast and Bay Islands	1,206	1,182	73	6·63
Burma, Inland	2,942	1,392	77	7·82
Bengal and Orissa	2,103	1,631	86	21·87
Gangetic Plain and Chutia-Nagpur	6,976	1,131	86	14·76
Upper Sub-Himalayan	12,749	1,226	75	14·12
North-Western Frontier, Indus Valley, and North-Western Rajputana.	4,781	1,115	59	15·06
South-Eastern Rajputana, Central India, and Gujarat.	6,151	1,131	78	14·96
Deccan	9,939	1,186	78	9·56
Western Coast	1,611	935	70	9·31
Southern India	3,194	1,354	80	14·40
Hill Stations	9,525	845	55	10·50
Hill Convalescent Depôts and Sanitaria ...	3,272	1,191	79	14·06

Of the above 12 groups, eight returned a higher daily sick-rate than that for the Army as a whole, and in seven groups the death-rate was greater. The most unhealthy group was Bengal and Orissa, with a daily sick-rate of 86 per 1,000 and a death-rate of 21·87, or about seven per 1,000 above its mortality (14·70) in 1898.

Of the stations with a strength of over 1,000, the highest death-rates were those of Peshawar (21·59), Lucknow (19·90), Umballa (17·39), and Bangalore (17·35). The first three were among the highest in 1898, but their ratios in 1899 were greatly reduced especially that of Peshawar, which was 48·95 in 1898.

Cholera.—There was again very little cholera in the European Army in 1898. Only one case, which proved fatal, was recorded against 17 cases and 14 deaths in 1898. "Never before in the records of this Office," the Sanitary Commissioner with the Government of India observes, "has so low a mortality appeared."

Small-pox.—Among the whole of the European troops in India there were during the year under notice 14 cases of small-pox with one death. In the previous year there were only 2 cases and no death.

Fevers.—From intermittent fever the admissions to hospital among the European troops in 1899 were in the ratio of 235 per 1,000 of strength, against 394 in the previous year. The death-rate was also lower, viz., 0·28 per 1,000, against 0·30 in 1898.

From enteric fever the admissions fell from 2,498 or 36·9 per 1,000 of strength to 1,392 or 20·6, and the deaths from 689 or 10·07 per 1,000 to 348 or 5·14. The reason for this great decrease "is to be found, perhaps," the Sanitary Commissioner states, "not so much in the climatic conditions of the year, as in the facts that the influx of drafts from England was much smaller than usual, and that there was no field service." Of the four Commands Punjab recorded the highest mortality under this head, viz., 6·64, followed by Bengal 5·50, Bombay 4·66, and Madras 3·03. Among the larger stations with an average strength of over 1,000, Peshawar returned a death-rate from this fever of 9·87, Meerut 9·31, Umballa 8·97, Allahabad 8·79, Lucknow 8·76, Chakrata 8·70, Mhow 8·37, Agra 8·23, Bangalore 7·43, and Rawalpindi 7·37, and in the remaining large stations the death-rate ranged from 4·85 in Rainkhet to 0·91 in Fort William and *nil* in Fort Dufferin (Mandalay). As usual, young and unacclimatised soldiers were the chief sufferers; among those from 20 to 25 years of age the death-rate was 7·59 per 1,000,

against 13·46 in 1898, while among men between 25 and 30, and from 30 to 35, the mortality was 3·08 and 1·72 per 1,000 respectively. Among men of less than one year's residence in India the death-rate from this fever was 11·72 per 1,000, among men between one and two years 6·81, and among men between five and ten years' service 2·63 per 1,000. Of the total 348 deaths from enteric fever, 73 per cent. occurred among men between the ages of 20–25, and 41 per cent. during the first year of residence in India.

Bowel Complaints.—The admissions from dysentery and diarrhœa among the European troops were in the ratio of 43 per 1,000 of strength, or 14 per 1,000 less than in 1898. The mortality from dysentery was in the ratio of 0·65 against 0·78 in the previous year, and from diarrhœa *nil* against 0·04. Dysentery was most prevalent, as usual, in the Bengal Command.

Abscess of the Liver.—From abscess of the liver there were 85 deaths, yielding a ratio of 1·26 per 1,000 of strength, against 1·52 in 1898.

Plague.—There were seven cases of plague among the European troops, and two of them were fatal, against nine cases and two deaths in 1898.

Venereal Diseases.—Venereal diseases ranked first in the list of causes of admission to hospital, and also in the causes of invaliding. They were the cause of 27 per cent. of the total sickness during 1899, and of over 20 per cent. of the invaliding of the European Army of India. The admission-rate from venereal diseases per 1,000 of strength was 313·4, or 49·5 per 1,000 below that of 1898, and 208 per 1,000 less than the maximum rate (522·3) recorded in 1895, "a practical proof," the Army Sanitary Commission remark, "of the success of the sanitary measures recently enforced with the object of preventing these diseases from spreading amongst our young soldiers in India." All four commands shared in the decrease, but it was most marked in Bombay and Bengal. The Madras Command returned the highest rate, viz., 397·8 per 1,000 against 438·3 in 1898. Bengal came next with a ratio of 364·9 against 437·9, Bombay with 273·6 against 352·5, and the Punjab with 226·7 against 268·9. The number of men constantly sick in hospital from these diseases was 1,851, against 2,202 in the previous year, being equivalent to about two regiments; and the average stay of a case in hospital was 32 days. The deaths from these diseases numbered 14, and the invalidings 442, against 17 and 569 respectively in 1898.

Invaliding.—The loss to the whole army by invaliding during 1899 amounted to 2,142 men, equal to 31·64 per 1,000, against 2,580 or 38·09 in 1898. The proportion of invalids to strength was highest in the Madras Command (38·7), followed by Bengal (35·7), Bombay (29·2), and Punjab (23·9). Of the total number invalided, 31 per cent. were discharged as unfit for further service, being 3 per 1,000 higher than in 1898. As regards the influence of age and length of residence in India upon invaliding, 59 per cent. of the total number invalided were under 25 years of age, against 62 in 1898, while 38 per cent. were of less than two years' service, and 81 per cent. were of less than five years' service. In the European Army of India as a whole 78 per cent. of the total strength had seen less than five years' service.

II.—NATIVE ARMY.

Sickness and Mortality in 1899.—The health of the Native Army of India was also better than in 1898.

The ratios of sickness and mortality among Native troops in the five Commands during 1899 and the previous year are given in the following table :—

Commands.		Average Strength.	Ratio per 1,000 of Average Strength.		
			Admissions.	Daily Sick.	Deaths.
Bengal	1898	25,036	767	35	10·03
	1899	26,820	716	29	10·03
Punjab	1898	42,515	942	35	13·38
	1899	44,224	731	27	12·48
Madras	1898	22,575	683	30	9·92
	1899	23,255	672	30	9·03
Bombay	1898	24,520	870	31	7·79
	1899	26,657	699	26	10·69
Hyderabad Contingent	1898	6,304	474	17	5·08
	1899	6,556	430	15	6·86
INDIA	1898	126,036	816	33	11·07
	1899	128,529	705	28	10·70

Of the five Commands the Punjab as usual returned the highest rate of mortality, though the ratio was slightly lower than that for 1898. Pneumonia was again very prevalent in this force, and the death-rate from it was 5·83 per 1,000, or nearly a half of the total mortality.

The chief cause of sickness in the Native Army was ague, which caused 37 per cent. of the total admissions. Among the diseases from which the admissions to hospital were higher than in 1898 were influenza, cholera and small-pox ; while from enteric and other fevers, respiratory diseases, bowel complaints, venereal diseases, &c., there was a decrease in the admissions. From influenza the admission-rate rose from 8·3 per 1,000 of average strength in 1898 to 12·3. From venereal diseases the admission-rate in the Native Army was only 34·1 per 1,000 of strength, as compared with 313·4 per 1,000 among European troops. Figures under this head are not available for the years before 1877. The ratios run at a much lower level than those of European troops, and they have remained comparatively steady during the 23 years, the ratios varying from 27·4 to 41·1.

Pneumonia was the chief cause of death in the Native Army, and no less than 36 per cent. of the total deaths were due to it. The death-rate under this head was 3·86 per 1,000 of average strength, against 3·77 in 1898. From this disease the mortality among the Native soldiers was nearly six times as great as that among European troops (0·66 per 1,000). Fevers of all kinds were the cause of 17·8 per cent. of the total deaths, against 44·0 per cent. among the European troops. From ague, remittent and simple continued fevers, the deaths among the Native troops were in the ratio of 1·89 per 1,000, while among the European troops the proportion was 0·46. On the other hand, the death-rate from enteric fever among the Native troops was only 0·02 per 1,000, as compared with 5·14 among the European troops.

From cholera there were 68 deaths in the Native Army, equal to 0·53 per 1,000 of strength, as compared with 42 or 0·33 in 1898.

During 1899 there were 76 cases of plague among the Native troops with 45 deaths, against 94 cases and 58 deaths in 1898.

Groups of stations.—The following statement gives the principal statistics of the Native Army, arranged in geographical groups, for 1899 :—

Groups.	Average Strength.	Ratio per 1,000 of Average Strength.		
		Admissions.	Daily Sick.	Deaths.
Burma Coast and Bay Islands	1,389	887	36	7·20
Burma, Inland	4,257	995	38	9·40
Assam	1,490	964	43	6·71
Bengal and Orissa	2,867	1,481	42	9·77
Gangetic Plain and Chutia-Nagpur	6,166	545	26	7·78
Upper Sub-Himalayan	15,555	554	24	9·90
North-Western Frontier, Indus Valley, and North-Western Rajputana.	16,269	839	32	15·31
South-Eastern Rajputana, Central India, and Gujarat.	12,522	583	22	6·71
Deccan	19,410	618	22	9·43
Western Coast	3,306	755	30	9·98
Southern India	8,075	597	33	7·55
Hill Stations	18,339	880	39	15·54

In eight of the 12 groups the daily sick-rate was higher than that for the whole Native Army, and in two the mortality was greater. In the previous year the highest mortality was recorded by the Assam group, viz., 27·15, of which cholera contributed 8·4 ; while in 1899 this group returned a death-rate of 6·71, cholera being entirely absent.

Of the large stations with a strength of over 1,000, the following recorded the highest death-rates :—Edwardesabad 28·04, Peshawar 16·19, Dera Ismail Khan 16·27, Belgam 15·24, and Mardan 10·96. The chief cause of death at these five stations was pneumonia.

OFFICE

III.—GENERAL POPULATION.

The year 1899 was generally a healthy one, though the failure of the monsoon rains in Western and Central India changed the climatic conditions of the last quarter for the worse, and terminated the prosperity which the two previous years had established.

Vital statistics.

Births were registered throughout all the 10 provinces in India in 1899, and the birth-rates varied between 50·5 and 25·6 per 1,000 of population under registration. All the provinces returned a higher birth-rate than in 1898, the improvement being attributed chiefly to their having recovered from the effects of the famine and scarcity of 1896–97, and to the healthiness and prosperity of 1898. The highest rates were recorded in Berar, the Punjab, the North-Western Provinces and Oudh, Central Provinces, Bengal, and Lower Burma, their respective rates being 50·5, 48·4, 48·1, 47·3, 42·9, and 37·0. In the remaining provinces the birth-rates ranged between 36·4 in Bombay and 25·6 in Coorg. The birth-rates exceeded the death-rates in all the provinces except Coorg, the excess per 1,000 varying between 19·26 in the Central Provinces and 0·7 in Bombay. The recorded deaths rose from 5,676,833 or 26·56 per 1,000 of registered population in 1898 to 6,418,409 or 29·95. The year 1898, however, was extraordinarily healthy, and the 1899 death-rate of 29·95 compares favourably with earlier years of the decade. Compared with 1898 the increase in mortality in 1899 was due to the greater prevalence of all the chief diseases except small-pox. In six of the ten provinces the mortality was higher than in the previous year. Cholera deaths rose from 151,509 to 169,236. The increase was confined to five provinces, but only three recorded cholera death-rates of over 1 per 1,000, viz., Assam 1·66, Bengal 1·51, and Lower Burma 1·11. The rise in the deaths from fevers by 355,784 was confined to five provinces, viz.: Bengal, North Western Provinces and Oudh, Central Provinces, Bombay and Berar. In connexion with this cause of death the scheme for the sale of quinine at a low price by postal agency does not on the whole appear to have achieved much success during the year.

The deaths from the chief diseases and from all causes in the several provinces were as follows:—

	Cholera.		Small-pox.		Fevers.		Dysentery and Diarrhœa.		Deaths from all Causes.		
	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000.	Total Deaths.	Ratio per 1,000 of Population under registration.

Bengal.

The general health of Bengal in 1899 was slightly above the average. The number of births registered in the province rose from 2,543,701 or 35·79 per 1,000 of population in 1898 to 3,053,178 or 42·96, the latter being made up of district rates varying from 53·28 in Palamau to 30·17 in Hooghly and 16·14 in Calcutta. Of the 46 districts there was an increase of births in all except Jalpaiguri, Rajshahi and Jessore, the greatest advance being in Hazaribagh, where the ratio was 18·09 per 1,000 in excess of the previous year. Three districts returned a birth-rate of over 50 and 29 of over 40 per 1,000, the highest, as already stated, being 53·28 in Palamau. Calcutta, as usual, returned the lowest birth-rate, but the sudden drop in 1898 noticed in last year's report as being probably due to an exodus of women from fear of plague, was almost counterbalanced by the rise from 13·98

to 16·14. Twenty-six towns returned a birth-rate in excess of 40 per 1,000, while 116 rural areas recorded rates of over 50 per 1,000, and 131 others over 45 per 1,000. These figures are considerably in excess of those of the three preceding years, and show how widely distributed was the increase in the general birth-rate for the province.

The total number of deaths registered during the year under notice was 2,218,243 or 31·21 per 1,000, as compared with 1,888,468 or 26·57 in 1898. There was thus an excess of births over deaths of 834,935 or 11·84 per 1,000. The district death-rates ranged from 50·75 in Malda to 19·97 in Singhbhum. In urban areas the rate of mortality rose from 27·50 to 33·10, which was made up of ratios varying from 69·18 in Puri to 12·07 in Manicktolla. In rural areas the average death-rate rose from 26·52 to 31·11. The death-rate, though much higher than that recorded for 1898, was lower than that of any of the four years which preceded it.

From all the principal diseases except small-pox the mortality was higher than in 1898. Cholera prevailed with greater intensity, and the deaths rose from 65,020 or 0·91 per 1,000 to 107,678 or 1·51, which was the second lowest death-rate from the disease on record for 14 years. No district entirely escaped the disease, and it attacked 17,217 villages against 11,307 in the previous year. Of individual districts the mortality was highest in Malda (6·28 per 1,000), followed by Puri (4·59), and Bogra (4·45). The high rate of mortality in Puri was chiefly due to a severe outbreak of the disease among the pilgrims during the Rath Jatra festival in July. As regards the seasonal incidence of the disease, the mortality was highest in the last three months of the year, and lowest in June, February, March and July.

From small-pox the deaths fell from 14,269 or 0·20 per 1,000 in 1898 to 13,116 or 0·18 in 1899. The disease was present in all the districts except Jalpaiguri and Pabna, the former having now been free from this scourge for three years in succession. The only districts in which it can be said to have prevailed in an epidemic form are Puri and Cuttack, with death-rates of 3·93 and 2·45 respectively. In no other district did the death-rate under this head reach 1 per 1,000.

About three-fourths of the total deaths were recorded under fever. The mortality, although higher than in 1898, was lower than in any of the four preceding years. The number of deaths reported to have occurred from fever during the year was 1,607,279 or 22·61 per 1,000 of population, against 1,479,483 or 19·97 in 1898. Out of the 46 districts, 20 recorded a higher fever mortality than the provincial rate, eleven registering a rate of over 30 per 1,000. Malda ranked first with a rate of 41·68, followed by Dinajpur 37·50, Faridpur 37·32, and Rajshahi 36·23, all of which, besides 35 others, showed an increase on the previous year's figures. In 29 out of the 39 districts which returned a higher fever mortality, there was a corresponding increase in the sale of quinine. In the two previous years there had been a considerable falling off in the sale of quinine packets, but in 1899 there was an increase of 8,423 on the number sold in 1898.

From dysentery and diarrhœa the mortality was somewhat larger, 41,334 deaths having been registered, equal to 0·58 per 1,000 of population, against 37,158 or 0·52 in the previous year. The increased prevalence of the disease, Dr. Dyson observes, was probably due, to some extent, to the causes which led to increased cholera in many districts, viz., early cessation of the rains and the early pollution of the water supply. The incidence of the disease was higher than that of the preceding year in 29 districts out of 46, lower in 15, and the same in two districts.

Plague was present in the province throughout the year, and the total mortality recorded from it was 3,264. All the deaths with the exception of 583 occurred in Calcutta. In all places, it is stated, the first patient was found to have come from Calcutta. The largest number of deaths in any one district (132) was reported from Saran.

In Calcutta the birth-rate was higher than that of 1898, viz., 16·14 against 13·98. The registered deaths numbered 25,823 or 37·8 per 1,000 of population, against 20,343 or 29·08 in the previous year. There was an increase in mortality under all the chief death causes except small-pox, from which there were only 62 deaths against 85 in 1898. Cholera deaths rose from 665 to 990, of which 107 or 10·8 per cent were imported from places beyond the limits of Calcutta, and 101 or 10·2 per cent. were pilgrims on their way home from Puri. The deaths from fever rose from 6,160 or 8·8 per 1,000 to 7,173 or 10·5. From plague 2,681 deaths were registered in the city against 192 in 1898.

North-Western Provinces and Oudh.

In the North-Western Provinces and Oudh the general sanitary conditions of 1899 were not up to the standard of the preceding year, but were well above the decennial average. During the year 2,255,627 births were recorded, being equal to 48·09 per 1000,

against 1,751,725 or 37·35 in the previous year. The birth-rate of the year is the highest on record, the rate previously highest being 43·77 in 1884. Of the total 48 districts 24 showed a birth-rate above and 24 below the average of the provinces. Bulandshahr, as usual, headed the districts with a birth-rate of 63·48, followed by Etah 61·44, Budaun 59·24, Muzaffarnagar 55·97, Hardoi 55·51, Aligarh 55·14, Farukhabad 54·90, and Bareilly 54·86. The birth-rate in municipalities was 47·24, against 36·44 in the previous year, and was made up of extremes ranging from 67·99 in Kandhla to 11·58 in Mussoorie.

The number of deaths registered was 1,556,821 or 33·19 per 1,000 of population, against 1,284,319 or 27·38 in 1898. The provincial death-rate, which was made up of district rates ranging from 41·93 in Mainpuri to 21·24 in Banda, was exceeded in 28 districts. The urban death-rate was 39·04 against 33·41 in 1898. Out of 104 municipalities only 18 recorded more deaths than births. Registration was again tested by local authorities, and the results disclosed an omission of 2·67 per cent. on 255,170 births, and 2·38 on 185,216 deaths; and in cases tested by the Vaccination Department the omitted percentages were 0·66 of births and 0·41 of deaths.

Cholera was more prevalent than in 1898, but with the single exception of that year the mortality was the lowest recorded since 1881. The total deaths from the disease numbered only 8,142 or 0·17 per 1,000, against 2,508 or 0·05 in 1898. Garhwal recorded the highest district rate of 1·61, followed by Fyzabad 1·19, and Dehra Dun 1·16, these being the only cases in which the death-rate exceeded 1 per 1,000. Four districts were entirely free from the disease, and no outbreak occurred at any of the large fairs. Out of a total of 107,239 villages only 1,049 were visited by cholera. The mortality was lightest in January (27 deaths), and heaviest in August (1,650). The disease declined in September, and in December 734 cholera deaths were reported.

The absence of small-pox was even more marked than in 1898, the mortality having fallen from 2,419 or 0·05, to 2,096 or 0·04, which is the lowest rate recorded since 1871, when trustworthy registration began. No high rates were reported in the districts, and three escaped the disease altogether. Hardoi and Gonda headed the districts with 0·17 each, and among towns Mallawan in the former district came first with 0·76.

The mortality from fever in 1899 was much higher than in the previous year, the number of deaths having risen from 1,063,596 or 22·67 per 1,000 to 1,245,260 or 26·55. Among the districts, Mainpuri came first with a fever death-rate of 40·09, followed by Farukhabad 37·75, Naini Tal 37·32, Muttra 35·89, Budaun 35·40, and Bulandshahr 35·23. Nineteen other districts recorded ratios above the provincial rate. The mortality reached its maximum in September and the minimum was in February. In addition to the sale of quinine at a low price by postal agency a scheme was under the consideration of Government for its sale through landholders and other non-official agency.

The deaths from dysentery and diarrhœa rose from 23,574 or 0·50 per 1,000 in 1898 to 27,206 or 0·58. Among districts, Garhwal again recorded the highest ratio of 8·79, followed by Almora 5·17, Dehra Dun 3·35 and Benares 2·11. In 12 other districts the provincial rate was exceeded.

The provinces were almost free from plague during the year, only seven deaths having occurred in Allahabad district. In the previous year 148 deaths were reported in the provinces.

Punjab.

The year 1899 in the Punjab was again a healthy one. The number of births registered was 994,001 or 48·4 per 1,000 of population, as compared with 841,869 or 41·0 in 1898. The birth-rate was again higher than that of any other province in India, and was made up of district ratios ranging from 69·1 in Jhang to 21·7 in Simla, and 30·4 in Peshawar. In 12 other districts the birth-rates ranged between 61·2 and 50·3 per 1,000. These high birth-rates are attributed chiefly to under estimation of the increase in population since the last census, to improved registration, and to the general healthiness of the preceding year. In 14 districts the birth-rate exceeded the provincial rate, and 13 other districts recorded ratios between 48·3 and 40·5 per 1,000. The provincial birth-rate exceeded the death-rate by 19 per 1,000 of population; in one district (Gujranwala) the excess was over 30 per 1,000; in 13 over 20 per 1,000, and in seven other districts the increase of births over deaths ranged between 15 and 18 per 1,000.

From all causes 607,725 deaths were registered, giving a death-rate of 29·57, against 638,124 or 31·05 in 1898. The highest district rates were reported from Jhang 41·6,

Karnal 35·3, and Gurgaon 35·0 ; the remainder varied between 34·4 in Delhi and 20·3 in Montgomery.

The province was practically free from cholera in 1898, only 33 deaths having been recorded, but in the year under notice the disease appeared in several districts, causing a mortality of 1,816, or 0·09 per 1,000 of population. More than half the deaths were contributed by Shahpur (702) and Hissar (308). Ten of the 31 districts were entirely free from the disease, and in six others only one or two deaths were recorded in each. Not a single cholera death occurred during the first three months of the year, and only four during the next three months. In July there were 71 fatal cases, followed by 433 in August ; there was a falling off till December, when the maximum number of 906 was registered. The disease was confined to 127 villages out of a total of 38,548.

Small-pox caused a mortality of 5,149 and a death-rate of 0·25, against 4,998 or 0·24 in 1898. All the districts were affected except Simla, but the disease was severe only in Peshawar, which is the least vaccinated district in the province, and which contributed no less than 2,288 deaths, giving a death-rate of 3·37 per 1,000. The mortality was excessive in the town of Peshawar, which recorded 770 deaths, being at the rate of 12·21 per 1,000. Of the total 5,149 deaths from this disease, all but 382 were children between the ages of 1 and 10.

The mortality from fevers was less than in 1898, though it was as usual severe. The deaths numbered 381,689, equal to a death-rate of 18·57 per 1,000, against 418,206 or 20·35 in 1898. The provincial rate was exceeded by 14 out of the total 31 districts, the highest being Jhang 24·06, Karnal 23·64, and Gurgaon 23·29.

From dysentery and diarrhœa the deaths fell from 15,747 or 0·77 in 1898 to 13,410 or 0·65. Thirteen districts recorded a higher mortality under this head than the provincial rate, the highest being Gurgaon 1·38, Simla 1·31, Kangra 1·30, Delhi 1·29, Hissar 1·12, Hoshiarpur 1·05, and Gurdaspur 1·03.

Plague was present in the province during the year and 255 deaths were recorded, against 1,951 in the previous year. Only four districts were affected, viz., Jullundur, Hoshiarpur, Rawalpindi, and Amritsar, but the disease was chiefly confined to Jullundur.

Central Provinces.

The year 1899 was again a very healthy one in the Central Provinces. The recovery of the people from the effects of the famine noticed in the previous year was continued in 1899. A total of 497,419 births was registered, being equal to 47·35 per 1,000 of population, against 313,116 or 29·75 in 1898. The increase was distributed over all the 20 districts ; and in all there was an excess of births over deaths ranging from 13·51 in Balaghat to 26·08 in Murwara. By districts the birth-rates ranged from 60·06 in Burhanpur to 38·58 in Saugor. The provincial birth-rate was exceeded in eleven districts.

The deaths during the year numbered 291,054 or 27·65 per 1,000, against 246,360 or 24·30 in 1898, which was an exceptionally healthy year. Still the mortality in 1899 was below that of any year in the past decade, except 1893 and 1898. In the last quarter of the year, when famine again declared itself, the mortality was less even than in the preceding healthy year. The provincial death-rate was exceeded in eleven districts, with ratios varying between 46·15 in Burhanpur and 27·88 in Bhandara ; in the remaining eight districts the death-rates ranged from 27·20 to 23·05.

There was again very little cholera in the provinces during the year, only 76 deaths having been recorded against seven in 1898. One death occurred in April and one in October, and 10 in November and 64 in December in Nimar district and the neighbouring Burhanpur sub-division. In each of the two previous years (1897 and 1896) over fifty thousand cholera deaths had been registered.

Small-pox was slightly more prevalent than in the previous year, and the deaths rose from 1,149 or 0·11 per 1,000 in 1898 to 1,511 or 0·14. The disease affected every district but two (Narsinghpur and Burhanpur), but only in one district did the death-rate reach 1 per 1,000, viz., Sambalpur, with 1·16. Of the total small-pox deaths 431 occurred among infants and 462 among children between one and 10 years of age.

The deaths ascribed to fevers numbered 168,326 or 15·98 per 1,000 of population, against 164,999 or 15·68 in 1898. The number of deaths and the death-rate were both much less than in any of the previous years from 1891, except 1898. The provincial death-rate from fever was exceeded by eleven districts, with ratios ranging from 37·40 to 16·15.

From dysentery and diarrhœa the registered mortality rose from 13,038 or 1·24, per 1,000 of population in 1898 to 13,489 or 1·28. The lowest death-rate under this head

was again recorded by Bhandara district (0·09), and the highest by Sambalpur (4·63). The other districts with relatively high rates were Wardha (4·17), Jubbulpore (2·01), and Burhanpur (1·98).

During the year there were 584 deaths from plague against 131 in 1898. Only two of the deaths were imported cases, the rest being indigenous. The disease did not succeed in establishing any firm hold in the provinces, as attacks were confined to the two districts of Nagpur and Wardha. Precautions were taken to prevent the disease spreading, and arrangements were everywhere made to cope with it in the event of its appearance.

Burma.

Registration of vital statistics continues to make steady progress in Burma. Births and deaths continued to be recorded in Lower Burma and registration has now been extended to 13 municipal towns in Upper Burma. Registration of deaths was introduced in selected districts in Upper Burma in the beginning of 1899, but it has been decided not to attempt for the present the registration of births. In the area under registration in Lower Burma 165,229 births were recorded in 1899, giving a birth-rate of 37·04 per 1,000 of population, as compared with 153,838 or 34·11 in 1898. That there is still much room for improvement is shown in the variations in the district rates, which ranged from 46·08 in Pegu to 17·55 in Rangoon. The number of deaths registered was 121,771, representing a death-rate of 27·30 per 1,000 of population, against 117,856 or 26·13 in 1898. By districts the ratios ranged from 20·55 in Akyab to 44·03 in Rangoon.

Cholera in an epidemic form prevailed throughout each month of the year and caused 4,942 deaths or 1·11 per 1,000 of population, against 2,972 or 0·66 in 1898. All the districts were visited by the disease except Toungoo. Mergui suffered more than any other district, and recorded a cholera mortality of 5·04 per 1,000, followed by Amherst with 2·47 and Myaungmya with 2·08. Seven per cent of the 16,757 villages were affected, against 4 per cent in 1898. The months of greatest mortality were April, May, and August.

Small-pox was more fatal than in 1898, the deaths having risen from 4,826 or 1·07 per 1,000 to 5,891 or 1·32, this being the highest mortality recorded since 1884. Of the 5,891 deaths, 686 or 11·6 per cent. were infants and 2,286 or 39 per cent. were children over one and under 10 years of age. The Pegu division again suffered most, its five districts returning 3,013 deaths, of which Rangoon contributed 919 or 5·10 per 1,000 of its population. The provincial average was exceeded in six other districts with rates varying between 2·61 and 1·43. Akyab district was free from small-pox during the year, and only two deaths were returned by Mergui.

Deaths ascribed to fever fell from 53,697 or 11·90 per 1,000 in 1898 to 51,177 or 11·47, which was made up of district rates ranging from 18·02 in Sandoway to 7·40 in Hanthawaddy. In ten other districts the provincial rate was exceeded. The town death-rate from fever was 8·12, and the rural rate 11·97, as compared with 8·23 and 12·45 respectively in 1898. In only five towns was the mortality above the average for the province, Myungmya coming first with 30·04, followed by Sandoway with 15·80.

The deaths registered under dysentery and diarrhœa during the year aggregated 8,071, or 39 more than in 1898, the death-rates being 1·81 and 1·78 per 1,000, respectively. By districts the highest mortality under this head was recorded by Tavoy 5·45, followed by Thaton 5·34, Mergui 4.75, and Rangoon 3·99; in the remaining 14 districts the death-rates ranged from 2·07 to 0·86.

Assam.

Registration of vital statistics is still imperfectly carried out in Assam. The total number of births registered during the year 1899 was 179,027, giving a ratio of 35·45 per 1,000 of population, as compared with 148,956 or 29·46 in 1898. The improvement was more marked in the two districts of the Surma Valley (Cachar and Sylhet), and "affords further proof" the Sanitary Commissioner reports, "that the people have recovered from the frightful malarial fever which did so much harm in 1897." The highest birth-rate was again recorded by Goalpara district, viz., 41·43, followed by the Garo hills (selected areas) 41·23, Cachar 39·35, Sylhet 38·02, and Lakhimpur 37·72, these being the only five instances in which the provincial rate was exceeded, as the rates of the remaining districts ranged from 34·43 in Darrang to 21·01 in Nowgong.

On the whole there was a marked improvement in the health of the province, and the registered deaths fell from 182,763 or 36·15 per 1,000 of population in 1898 to 156,595, to 31·01 per 1,000. No district except Darrang registered so high a death-rate as in the previous year. In the Surma Valley, comprising the districts of Cachar and Sylhet, the average mortality fell from 37·29 to 30·53, and in the Brahmaputra Valley the average death-rate was 31·01, as compared with 36·17 in the previous year. Of the six districts

in this division Darrang recorded the highest mortality of 44·86 per 1,000, the ratios of the remaining five districts ranging from 38·83 to 23·58. Taking the province as a whole an excess of births over deaths to the extent of 4·44 per 1,000 was reported, whereas in the previous year the death-rate exceeded the birth-rate by 6·69.

The mortality from cholera was still less than in 1898, the number of deaths being 8,380 or 1·66 against 11,288 or 2·24 in 1898. The disease prevailed throughout the year and visited every district. The highest district cholera death-rate was recorded by Goalpara (5·05 against 1·86 in 1898) in the Brahmaputra Valley, followed by Kamrup and Darrang whose rates were respectively 2·08 and 1·70. The average death-rate from cholera in the towns was 1·71 per 1,000, against 1·66 in rural areas. Among tea-garden coolies who travelled up the Brahmaputra Valley in steamers there were 21 deaths from cholera, against 26 in 1898; and among the coolies at the depots, after landing, there where 51 deaths, against 58.

The mortality from small-pox was much less than in the previous year, the deaths numbering only 1,565 or 0·31 per 1,000, against 5,208 or 1·03. No less than 80 per cent. of the deaths occurred in the Brahmaputra Valley districts, where there is still a very strong objection to vaccination. Out of 1,258 small-pox deaths in these districts, Darrang contributed 946 or 3·07 per 1,000 of population. The next highest mortality was in Khasia, and Jaintia Hills, viz., 2·24. In no other district did the death-rate from this cause reach 1 per 1,000. Of the total small-pox deaths, over 65 per cent. occurred among children under 10 years of age.

More than a half of the year's mortality was ascribed to fevers, including kala-azar. The number of deaths registered from these causes was 91,096, representing 18·04 per 1,000 of the population, against 105,811 or 20·95 in 1898. The decrease was chiefly in the Surma Valley, where the death-rate fell from 18·59 to 14·83. Of the 91,096 fever deaths 14,246 were from kala-azar against 16,472 in 1898. The provincial fever death-rate was exceeded by four districts, Goalpara ranking first with a rate of 30·11. As in previous years, the bulk of the kala-azar deaths occurred in Nowgong district, but there was a marked improvement on the previous year's figures, the number of deaths having fallen from 10,515 to 8,192. In Darrang the mortality under this head remained about the same (4,101), while Kamrup showed a slight increase (1,745 against 1,693). On the whole, the Sanitary Commissioner states, the epidemic may be said to be surely if slowly ceasing.

The improvement in general health is also shown by the decreased number of deaths from dysentery and diarrhœa, the figures having fallen from 16,239 or 3·23 per 1,000 of population to 13,835 or 2·74. The district rates presented the same extraordinary and unaccountable differences as in former years. Thus in Goalpara the rate was 0·33, and in Kamrup and Nowgong 1·09, while in Darrang, Sibsagar and Lakhimpur the rates were 4·44, 5·65, and 7·70 respectively. The difference however was thought to be more apparent than real and to be caused by differences in registration.

Madras.

The number of births registered in Madras Presidency during the year was 1,048,335 or 31·3 per 1,000, against 911,747 or 27·4 in 1898. The increase was attributed partly to better registration and partly to the natural tendency to an increase of birth-rate among the population inhabiting the districts which had suffered from famine during the preceding years. The rates for urban and rural areas were 35·7 and 30·9 against 33·0 and 26·9 respectively in the previous year. With a view to improvement in rural areas, an Act entitled the Madras Registration of Births and Deaths Act was passed during the year and is at first to be worked tentatively in selected rural areas. Kistna district registered the highest ratio of 40·5, and in twelve other districts the rate was above 30 per 1,000; in all but five of the 22 districts there was an increase in the birth-rate.

The mortality in 1899 was less than that of the previous year by 24,014, the deaths having fallen from 699,108 or 21·0 per 1,000 to 675,094 or 20·1. By districts the highest death-rate (38·5) was recorded in Madras City, though it was nearly 7 per 1,000 lower than that recorded in the previous year. In the other districts the mortality ratios ranged from 29·9 per 1,000 in South Canara to 14·4 in Ganjam. The Sanitary Commissioner (Dr. King) remarks that "it is hopeless to attempt, under existing circumstances of registration, to criticise the death-rates reported from districts. They may possibly sink to the almost certainly ridiculous rate of 14·4 per 1,000 in Ganjam, or rise to nearly 30 per 1,000 in South Canara without its being possible to state definitely what are the errors of omission and commission. The only criterion available is the approach to accuracy of the birth-rate, and the acknowledged existence of special diseases. One cause of deficient death-rate is certainly a tendency to ignore the deaths of infants below one year of age."

Of the chief diseases, cholera showed a further decline, the number of deaths having fallen from 65,444 or 2·0 per 1,000 to 29,082 or 0·9. All the districts but two (Kurnool and Nilgiris) were affected. In three other districts the deaths did not exceed 20 altogether. The disease was most severe in Salem, Tanjore, and Trichinopoly, which recorded cholera death-rates of 2·8, 2·6, and 2·4 respectively. In the remaining districts the rates varied from 1·9 in South Arcot to 0·01 in Anantapur. The average death-rate in municipal and other towns from the disease was 1·5 per 1,000, against 2·1 in 1898, and that in rural tracts 0·8, against 2·0. Twenty-eight of the municipalities were free from cholera, while three recorded death-rates over 10 per 1,000, and four over 5 per 1,000.

Small-pox deaths were reported from all the districts, and the total in the whole Presidency aggregated 16,991 or 0·5 per 1,000, against 20,490 or 0·6 in 1898. Of the districts, South Arcot was the only one in which the mortality exceeded 1 per 1,000 (1·2). It is satisfactory to observe that Ganjam returned only 489 deaths from the cause, against 10,838 in the previous year. Of the total small-pox deaths, 5,702, or 33½ per cent., occurred amongst children under 1 year of age, and 5,286, or 31 per cent., among those between 1 and 10 years of age.

From fevers the registered deaths fell from 248,638 or 7·5 per 1,000 of population in 1898 to 245,549 or 7·3. Dr. King attributes the reduction partly to the imperfect character of the north-east monsoon and the consequent absence of the usual degree of moisture in the soil, and partly to a tendency on the part of those giving information regarding deaths to escape suspicion of a disease whose prominent symptom is fever, namely plague. In ten districts, however, the fever death-rate was higher than in the previous year. Seven districts had death-rates of over 10 per 1,000, and six of over 5 per 1,000. Six of the 59 municipal towns returned fever death-rates exceeding 10 per 1,000, the highest being 13·7 in Cuddapah and 13·0 in Kurnool.

The number of deaths registered under dysentery and diarrhœa in the Presidency was 31,307 or 0·93 per 1,000, against 29,654 or 0·89 in 1898. Of the districts, Madras as usual came first with a death-rate from this cause of 7·9, against 7·5 in the previous year, followed by Chingleput with 3·0, and Bellary with 1·9; three other districts had rates over 1 per 1,000. Of the towns, Gudiyattam recorded the high death-rate of 8·6 per 1,000, followed by Vizianagram, 8·4, Madras, 7·9, Walajapet, 7·7, Vizagapatam, 7·6, Tuticorin, 7·4, and Chingleput, 7·1, in all of which "either the conservancy arrangements are defective or the water supply is open to contamination."

Plague was imported into the Presidency towards the close of the previous year, and eleven districts were more or less affected. Precautionary measures were promptly taken, and the spread of the disease was, as a rule, successfully prevented. By the end of the year 711 attacks with 557 deaths had been reported. In 1899 the attacks rose to 2,385 and the deaths to 1,843.

Bombay.

In the Bombay Presidency, including Sind, 685,348 births were registered during the year, giving a birth-rate of 36·42 per 1,000 of population, as compared with 582,371 or 30·94 in 1898. Of the 24 collectorates and districts all but four recorded higher rates than in the previous year. Bombay City, as usual, recorded the lowest rate, viz., 12·88, against 13·08 in the previous year, and Khandesh the highest, 52·85. In ten other districts the Presidency rate was exceeded.

The total number of deaths registered in the Presidency rose from 548,825 in 1898 to 672,269, and the rate per 1,000 of population from 29·16 to 35·72, which was made up of district ratios ranging from 69·54 in Bombay City to 13·87 in Hyderabad. The increase of 123,444 deaths was spread over all the districts except three. Poona district recorded the second highest death-rate (49·67), followed by Nasik with 49·62. Three other districts, viz., Broach, Belgaum, and Dharwar, had a death-rate above 40 per 1,000, and in 11 other districts 30 per 1,000 was exceeded. In several districts the high death-rates were due to plague.

From cholera the deaths during the year rose from 4,368 or 0·23 per 1,000 in 1898 to 8,579 or 0·46. All but 376 deaths occurred in the three districts of Belgaum (4,474), Karachi (2,394), and Dharwar (1335), their respective death-rates from this cause being 4·42, 4·27, and 1·27 per 1,000 of population respectively. The disease in its epidemic form was practically confined to these three districts. Twelve of the 24 districts were entirely free from the disease during the year, and in six other districts the deaths in each were below 10. Deaths from cholera occurred in every month of the year, the months of greatest prevalence being March, April and May, when 5,747 deaths occurred. Out of 220 rural circles only 26 were affected by cholera, and 12 out of 56 town circles.

Small-pox deaths were higher by 112, the number having risen from 1,834 in 1898 to 1,946, the death-rate (0·10) remaining the same. "These figures," the Sanitary Commissioner (Lieut.-Colonel Clarkson) observes, "may be considered very satisfactory, and they testify to the exceedingly good vaccination work which now for some years has been done in the Presidency." Six of the districts were free from the disease, and in no case did the death-rate reach 1 per 1,000, the highest rate recorded being 0·56 in Thana, the result of 456 deaths, Bombay City following with 439 deaths or 0·54 per 1,000. According to age, 28·37 per cent. of the small-pox deaths occurred among infants under one year of age, and 45·73 per cent. among children between the ages of 1 and 10.

The deaths registered in the Bombay Presidency as due to fevers were more numerous by 12,114, the number having risen from 216,324 or 11·49 per 1,000 of population in 1898 to 228,438 or 12·14. These numbers do not include deaths from plague, from which there were 86,191 in 1898 and 96,596 in 1899. The average fever death-rate was exceeded in 14 districts, among the highest being 24·57 in Broach, 22·41 in Thar and Parkar, 21·75 in Ahmedabad, and 21·44 in Panch Mahals. The fever death-rate was higher than in the previous year in 13 out of the total 24 districts.

The number of deaths ascribed to dysentery and diarrhœa also rose from 56,789 or 3·02 per 1,000 of population in 1898 to 74,736 or 3·97, a ratio which is considerably higher than in any of the 12 years preceding except 1897. In nine of the 24 districts the average death-rate under this head was exceeded, the highest being again recorded by Sholapur 9·60, followed by Khandesh 9·43, Poona 7·59, Nasik 7·44, Satara 5·95, and Bombay 5·28.

From plague 96,596 deaths were reported during the year, giving a ratio of 5·13 per 1,000 of population, against 86,191 or 4·6 in 1898. The outbreak commenced in September of 1896, at the end of which 2,086 deaths had been reported, being equal to a ratio of 0·12 per 1,000. Up to the end of 1896 ten of the 24 districts had remained free of the disease, but in spite of precautions to check its progress, plague extended to all but two (Kanara and Panch Mahals) of the districts by the close of 1897, though some were but slightly affected. In 1898 all the districts were affected but three in Sind. Of the 96,596 deaths in 1899, Bombay City contributed 15,874, a decrease of 2,256 on the number reported in 1898, and the death-rate fell from 22·49 to 19·69. Poona district followed with a rate of 17·94, Belgaum 12·63, and Nasik 10·03. Only one district, Thar and Parkar, remained uninfected throughout the year. An interesting account of the further progress of the plague, and of the measures taken to suppress it, will be found in the Abstract of the Report of the Sanitary Commissioner with the Government of India, at pages 91–117.

Berar.

The total number of births registered in Berar in the course of the year was 144,034 or 50·5 per 1,000 of the population, against 89,414 or 31·3 in the previous year, which was the lowest birth-rate on record. The increase was attributed chiefly to the improved vitality of the people in consequence of the bumper harvest of 1898, and a fall in the price of food grains. In all the six districts of the province the birth-rates were higher than in the previous year, and ranged from 54·3 in Akola to 45·8 in Basim. The births exceeded the deaths in all districts, the excess being greatest in Buldana, viz., 15·6 per 1,000.

The deaths rose from 66,806 or 23·4 per 1,000 of population in 1898 to 113,992 or 39·9. All districts contributed to the increase, the excess being most marked in Akola, where the rate (50·8) was more than double that of 1898 (25·1). The provincial death-rate was exceeded in the districts of Akola (50·8) and Ellichpur (45·6). There was an increase under all the registered heads of mortality, except small-pox, the largest increase (6·8) being under all other causes and fevers (6·0).

The province was entirely free from cholera in the previous year, and remained so until August, 1899, when the disease broke out in Amraoti district. The disease prevailed during each of the five months ending December but claimed only 541 victims, giving a death-rate of 0·2 per 1,000 of population. With the exception of 1898 the mortality was the lowest recorded since 1888, in which year there were only 305 deaths from cholera.

Small-pox was not so widespread or so intense as in 1898, and caused only 305 deaths as compared with 592 in 1898, the death-rate being 0·1 per 1,000 against 0·2. Nearly a half of the deaths (142) occurred in Wun district, and the fewest number (6) in Amraoti district. About 71 per cent. of the deaths occurred amongst children under 10 years of age, 71 or 31 per cent. being infants under one year.

Under fevers the mortality rose from 32,789 or 11·5 per 1,000 in 1898 to 49,938 or 17·5. The increase was general in all districts, the death-rate varying between 22·9 in Akola and 12·9 in Buldana. The Sanitary Commissioner (Dr. Swaine) observes that influenza "which was very prevalent in 1899 as compared with 1898, especially at the end of the cold and the commencement of the hot weather, served to increase the mortality under this head."

The number of deaths attributed to dysentery and diarrhœa rose from 9,942 or 3·5 per 1,000 in the previous year to 20,263 or 7·1. Akola district recorded the highest mortality under this head, viz., 11·4, against 4·4 in the previous year, Ellichpur following with 10·6, which was also higher than the ratio (5·0) of the preceeding year. The other district rates ranged from 7·1 in Amraoti to 2·4 in Wun. "The deficient and impure water-supply" Dr. Swaine remarks "would account generally for the increase in this disease."

Two cases of plague were reported in the province during the year. One was imported from Ahmednagar district in Bombay Presidency, and terminated fatally, the other, a suspicious case, also proved fatal.

IV.—JAILS.

Sickness and mortality in 1899.

In spite of the scarcity which began to make itself felt before the close of the year under notice, and which resulted in increased admissions to jails, the general health of the prisoners was very satisfactory in 1899. "The death-rate of a comparatively small floating population" the Director-General, Indian Medical Service, remarks, "such as that of our jails is so markedly affected by the exceptional influences which occasionally operate to the detriment of the health and life of the population at large (*e.g.* epidemics and famine) that the survey of the figures of a few years is of little value. If, however, we extend our observations to the records of the last 20 years, we find that there has been a fairly consistent advance in the control of the causes of sickness and mortality in nearly every provincial group of jails."

The daily average sick per 1,000 of average strength fell from 37·3 in 1898 to 31·4, the ratio of admissions into hospital from 917 to 792, and the death-rate from 25·34 to 21·86. In every province except Bengal, Bombay, Assam and Coorg, the jail death-rate was lower than in 1898, and in four provinces the rates were lower than in any of the previous five years. In Madras the rate was the lowest on record, in Bengal the rate was only 0·9 higher than the lowest recorded, and in the North Western Provinces and Oudh it was also with the exception of 1893 the lowest on record. There was again very little cholera among the prisoners, and the convicts in the Punjab, Berar, and Coorg jails were entirely free from the disease.

The following statement shows the sickness and mortality among all classes of prisoners in the jails and subsidiary jails of the several provinces for 1899, as compared with the previous year :—

Provinces.	1899.			1898.		
	Ratio per 1,000 of Average Strength.			Ratio per 1,000 of Average Strength.		
	Admissions.	Daily Sick.	Deaths.	Admissions.	Daily Sick.	Deaths.
Bengal	1,034	34	23·4	1,037	34	22·5
North-Western Provinces and Oudh.	792	38	22·2	921	47	28·7
Punjab	1,107	33	18·8	1,373	37	23·5
Burma	584	27	18·7	620	32	20·6
Central Provinces	863	27	24·4	1,134	51	34·6
Assam	982	73	48·0	1,185	54	36·6
Coorg	815	29	126·7	874	23	92·0
Madras	411	22	16·9	578	27	26·2
Bombay	599	25	25·2	756	27	21·3
Berar	445	13	13·8	581	16	14·9
India	792	31	21·9	917	37	25·3

Bengal.

The health statistics of the Bengal jails for 1899 are again exceedingly satisfactory. The admissions into hospital were in the ratio of 1,034 per 1,000 of average strength, against 1,037 in 1898, the average daily sick-rate (34 per 1,000) was practically the same, while the death-rate rose slightly from 22·5 to 23·4. These results are the more satisfactory as many parts of the province were very unhealthy and the death-rate among the general population rose from 26·57 per 1,000 in 1898 to 31·21. Among all classes of prisoners there were 448 deaths, and of these 402 were convicts. The diseases which contributed chiefly to the convict death-rate (23·0 per 1,000) were dysentery 103 deaths, respiratory diseases 99, pneumonia 50, and malarial fever 36. As in the previous year there were only three deaths from cholera. Of the 392 convicts who died in central and district jails (including four who died out of hospital), 28·57 per cent. were received in good health, 32·91 per cent. in indifferent health, and 38·52 in bad health. Out of 48 jails the average death-rate among convicts was exceeded in 22, the highest

being Barisal 62·0, Purnea 61·1, Faridpur 56·4, Suri 55·2, and Hooghly 54·9, and in three others the mortality rate was over 40 per 1,000. In four jails there were no deaths, and in five there was only one death in each.

North-Western Provinces and Oudh.

The sanitary history of the jails of the North-Western Provinces for 1899 is again satisfactory. There was a further improvement as regards the sickness and mortality, the admissions into hospital, which was the lowest recorded with the exception of that for the year 1893, having fallen from 921 per 1,000 of average strength in 1898 to 792, the daily average sick-rate from 47 to 38 per 1,000, and the death-rate from 28·7 to 22·2. Of the 55 jails in the province there were no deaths in one, and 19 others recorded death-rates below the provincial jail rate. The highest mortality (89·0) occurred, as usual, in Mirzapur district jail, followed by Banda 48·5, Ghazipur 46·0, besides Lalitpur and Pauri jails, in which the average was very small, and "the proportion of deaths is therefore not a sure criterion." The conditions of the Mirzapur jail have often been brought to notice and remedial measures undertaken ; but the Inspector-General does not believe that its unhealthiness depends on removable defects in the sanitation of the jail itself. He says that the site of the jail is bad and its surroundings hopelessly insanitary, and he suggests that a new jail should be built in a more healthy locality. Chief among the jails with a low mortality was Bareilly Central Prison, with only 8·8 per 1,000 on an average strength of 2,012 convicts. Only one fatal case of cholera was reported during the year. Of other diseases, dysentery was accountable for 144 deaths against 190 in 1898. From pneumonia there were 121 deaths against 135 ; other respiratory diseases were also less fatal than in the preceding year. Of the total 652 deaths 600 were of convicts, their death-rate being 21·8 per 1,000 against 28·8 in the previous year.

Punjab.

The health of the prison population of the Punjab greatly improved during 1899. The admissions to hospital per 1,000 of average strength fell from 1,373 in 1898 to 1,107, the daily sick-rate from 37 to 33, and the death-rate from 23·5 to 18·8. Only in three years since 1880 has the mortality been lower, which is the more satisfactory considering the unfavourable climatic conditions that prevailed in the province during 1897 and 1898. "The figures," the Inspector General states, "besides bearing testimony to the excellence of the medical work done will, I hope, encourage all officers immediately responsible for the welfare of the prisoners in our jails to persevere in their efforts to still further reduce preventable mortality. . . . I am persuaded that reasonable attention given to details affecting health, far from weakening discipline is calculated to strengthen it." The provincial death-rate was exceeded in 10 jails, the highest being 38·02 in Mooltan Central jail, 35·39 in Lahore Central jail, and 34·97 in Bannu district jail. In six jails there were no deaths. Of the total 251 deaths, all but 20 were of convicts, giving a death-rate of 19·12. A satisfactory feature of the year was the decline in the prevalence of dysentery, the deaths from which fell from 49 to 31. The most fatal disease was pneumonia, which contributed 63 deaths or 5 less than in 1898. The jails were again free from cholera during the year. More than half the deaths occurred from diseases of the lungs in one form or another.

Burma.

The Burma jail statistics for 1899 are much more satisfactory than those for the previous year, and show that the health of the prisoners had improved considerably. The admissions to hospital per 1,000 of average strength fell from 620 to 584, the daily sick-rate from 32 to 27, and the death-rate from 20·6 to 18·7. Of the 235 deaths which occurred during the year, all but 10 were of convicts, the death-rate being 18·44 against 20·39 in 1898. There were 42 cases of cholera with 24 deaths, which were spread over eight jails ; but the largest and only important outbreak occurred in Moulmein jail, which returned 19 cases and 11 deaths. In the previous year there were only three deaths from cholera. Eleven of the 31 jails recorded death-rates exceeding the provincial average, but in several cases the average strength was small. In eight jails there were no deaths among convicts. Moulmein retains its reputation for unhealthiness. Of the 40 deaths in this jail, 15 were from dysentery and 11 from cholera. The status of this jail has been lowered from that of a Central to that of a District jail.

Central Provinces.

The vital statistics of the jails of the Central Provinces for 1899 are very satisfactory, which however is not surprising, as the year is reported to have been an unusually healthy one. The ratios of admissions into hospital, of daily sick and of deaths, which in 1898 were 1,134, 51 and 34·6 per 1,000 of average strength, fell to 863, 27 and 24·4 respectively in

1899. Deaths diminished in the aggregate by nearly one half the number of the previous year, and Narsinghpur was the only jail out of the 19 in the province at which there was an increase in mortality. The average death-rate was made up of jail-rates varying from 60·0 in Narsinghpur to 7·0 in Hoshangabad. In five jails there were no deaths. All the jails were free from cholera except Bilaspur, where there was one death from it. Under all other causes the admissions were less than in 1898, and this was also the case with the deaths except under malarial fevers, where the deaths rose from 4 to 8, and under pneumonia, where the number of deaths was identical in both years. All but 10 of the 93 deaths occurred amongst convicts, the death-rate being 24·4, against 35·18 in 1899.

Among the prison population of Assam the rate of admissions to hospital fell from 1,185 per 1,000 in 1898 to 982 in 1899, the daily sick-rate rose from 54 to 73, and the death-rate from 36·6 to 48·0. The increase in the death-rate was chiefly due to a very severe outbreak of cholera in the Gauhati jail in October, which accounted for 18 deaths. Excluding cholera, the mortality was practically the same as in the previous year. In discussing the high mortality in the Assam jails, the Chief Commissioner suggests that it may be due to exposure involved in extramural labour, a point which he states must be thoroughly tested for at least two or three years. In only three of the 24 jails was the average strength above 100, viz., Sylhet, Tezpur, and Gauhati, and these three accounted for 70 out of the total 78 deaths. In the other jails the average strength varied from 8 to 62. In three jails there were no deaths. All but four of the 78 deaths occurred amongst convicts, being in the ratio of 49·73 per 1,000 against 35·43 in 1898. There were 26 cases of cholera with 18 deaths, all of which occurred in Gauhati jail; in the previous year there was only one death from this disease. From dysentery and diarrhœa there were 14 deaths, and from malarial fevers 15. Assam.

In the jails of Madras Presidency the general health of the prisoners during 1899 was very satisfactory. The hospital admission rate fell from 578 per 1,000 of average strength in 1898 to 411, the daily sick-rate from 27 to 22 per 1,000, and the death-rate from 26·2 to 16·9. The sick-rate was the lowest since 1891, and the rate of mortality was the lowest on record. These results are mainly attributable to the comparative immunity from serious epidemics and to the general healthiness of the Presidency, and to the care bestowed on sick prisoners by medical officers. As in 1898, there was a remarkable absence of epidemic cholera, only two deaths having been recorded from the disease; there was also a considerable reduction in the number of cases of dysentery, and the rate of mortality fell from 6·04 to 1·34. Pneumonia and other respiratory diseases were also less fatal. Of the larger or central jails, Trichinopoly was the only one in which the normal death-rate was exceeded, that for 1899 being 31·26 against 31·06 in the previous year. In 1898, the high mortality in the Rajahmandry Central Prison (193·14) called for detailed notice, but it is satisfactory to observe that there was a remarkable improvement in the health of the prisoners in the year under notice, the death-rate having fallen to 14·28. In none of the other jails, with a strength of over 200, did the mortality reach 30 per 1,000; while in five jails there were no deaths. Of the total 182 deaths convicts contributed 147, representing a ratio of 16·70 per 1,000 of average strength, as compared with 28·09 in 1898. Madras.

Although nearly all the jails in the Bombay Presidency were again overcrowded during 1899, the health of the prisoners was fairly good. The rate of admissions to hospitals per 1,000 of average strength fell from 756 to 599, the daily sick-rate (25) was 2 per 1,000 less, and the death-rate rose from 21·3 to 25·2 per 1,000. The death-rate was under 20 per 1,000 of average strength in ten jails, in three it ranged between 20 and 30; while those with rates over 30 were the Common Prison 120, Thana 71·6, and Dharwar 45·2. All but 39 of the total 276 deaths (including 27 in the lock-ups) occurred among the convicts, their death-rate being 25·9 against 22·5 in 1898. The chief causes of mortality were dysentery and diarrhœa 38 deaths, respiratory diseases 48, including 36 from pneumonia, fevers 13, and tubercle of the lungs, &c., 23. There were only seven cholera deaths, all of which occurred among the convicts in Dharwar jail out of a total mortality of 22. In spite of the prevalence of plague in the Presidency only 15 cases occurred among the prisoners, of which eight proved fatal, against 39 cases and 22 deaths in the previous year. The measures taken for preventing the dissemination of the disease were good and effectual, especially in Dharwar prison, plague having been very rife in the town and district for some months in the year. Bombay.

Berar.

The health of the jail population of Berar in 1899 was exceptionally good. The rate of admissions into hospital per 1,000 of average strength fell from 581 to 445, the daily sick-rate from 16 to 13, and the death-rate from 14·9 to 13·8. The fall in the death-rate is the more remarkable as among the general population the mortality rose from 23·4 per 1,000 to 39·9. There was no outbreak of epidemic disease in any of the jails, and cholera was absent. There were only 19 deaths, including one at Secunderabad, against 24 in 1898. All but one of the 18 deaths occurred in the larger jails at Akola and Amraoti, eight in the former and nine in the latter. There were no deaths in three jails. All but three of the 19 deaths occurred amongst convicts, their death-rate being 13·52 per 1,000, as compared with 15·28 in 1898.

V.—VACCINATION.

During 1899-1900 there were 7,437,916 persons successfully vaccinated in the several provinces of India, being an increase of 577,001 on the number of the previous year. After the falling off in the two preceding years, owing mainly to plague and famine, this increase must be considered satisfactory, and especially so as it was contributed to in varying degrees by all the provinces. According to age, nearly 3½ millions (3,449,012) of the total were children under one year of age, and nearly 3 millions (2,982,724) were children between the ages of one and six years. The proportion of population protected against small-pox by the year's operations ranged from 56·72 in Burma to 28·72 in Madras. In the vaccination of infants the best results were, as usual, obtained in Berar and the Punjab, followed by the Central Provinces and Bombay, where 83·00, 66·55, 60·18, and 56·30 per cent. respectively of the children born during the year (estimated at 40 per 1,000 of population) were protected against small-pox. In the North-Western Provinces and Oudh the percentage was 45·24, and in the remaining provinces it ranged from 40·14 in Burma to 11·70 in Coorg. General results.

Statement showing the total number of persons successfully vaccinated during the year 1899–1900 :—

Province.	Population among whom Vaccination was carried on (Census of 1891).	Number of Persons successfully vaccinated.	Ratio of successful Vaccinations per 1,000 of Population.	Number of Children successfully vaccinated.		Percentage of Children born during the Year (calculated at 40 per 1,000 of Population) successfully vaccinated.
				Under One Year of Age.	Between One and Six Years of Age.	
Bengal	70,974,023	2,176,895	30·67	619,068	1,353,939	21·81
North-Western Provinces and Oudh.	47,146,033	1,414,082	29·99	853,065	438,741	45·24
Punjab	20,553,982	820,506	39·92	547,113	127,657	66·55
Burma	8,146,855	462,102	56·72	130,822	210,525	40·14
Central Provinces	12,739,620	483,141	37·92	306,669	96,440	60·18
Assam	5,716,833	255,562	46·62	61,793	121,415	27·02
Madras Presidency	35,651,577	1,023,980	28·72	324,241	506,545	22·74
Bombay Presidency	22,612,220	666,871	29·49	509,251	108,851	56·30
Berar	2,897,040	125,311	43·2	96,180	14,285	83·00
Coorg	173,055	9,466	54·70	810	4,326	11·70
TOTAL	226,611,238	7,437,916	32·86	3,449,012	2,982,724	38·05

The total number of vaccinations performed in Bengal during 1899–1900 was 2,252,521 of which 2,176,895 were successful, against corresponding figures in 1898–99 of 2,147,452 and 2,085,904. This shows an increase of 105,069 vaccinations in 1899–1900, which, however, was confined to few districts, as there was a decrease in 21 districts, due in most cases to the prevalence of cholera, malarial fever, and plague, and to the general unhealthiness of the year. In some districts the work was retarded by the alarm occasioned by plague. The primary operations numbered 2,203,084, of which 97·67 per cent. were successful. According to age, 619,068 of the successful primary vaccinations were of children under one year of age, and 1,353,939 were between one and six years. For the whole province the successful vaccinations were in the proportion of 30·67 per 1,000 of the population. Estimating the births during the year at 40 per 1,000, the percentage of infants successfully vaccinated was 21·81, which is a little less than that for Madras, and far below that attained in other provinces except Coorg. Bengal.

Three methods of vaccination are practised in the province—(1) with lymph taken direct from the calf; (2) with calf lymph prepared with lanoline; (3) with human lymph taken by arm to arm transfer. Compared with the previous year's figures there was an increase of 35,000 in the number of primary operations performed direct from the calf.

North-Western Provinces and Oudh.

In spite of the fact that many experienced and senior vaccinators were again in several districts employed on plague duty and were replaced by new and inexperienced men, the number of persons vaccinated in the North-Western Provinces of Oudh during 1899–1900 rose from 1,398,684 in the previous year to 1,511,436. The increase was spread over 41 districts and ranged from 9,261 in Gorakphur to 182 in Etawah. The proportion of persons protected by vaccination is still very small, the ratio for the year being only 29·99 per 1,000. Primary vaccinations numbered 1,449,653, of which 97·00 per cent. were successful. Of the 1,365,931 successful primary cases, 853,065 were infants and 438,741 were children over one and under six years of age. Estimating the birth-rate at 40 per 1,000 of the population, 45·24 per cent. were successfully vaccinated during the year.

The provinces are divided into two circles for the purposes of control, each being in charge of a Commissioned Medical Officer, acting as Superintendent of Vaccination and Deputy Sanitary Commissioner. In the first or western circle, the average ratio of successful vaccinations was 31·58 per 1,000 of the population. In the second or eastern circle, the average ratio was 28·59. The Vaccination Act is in force in all the municipalities, but the thoroughness of enforcement still varies considerably. There was however an increase of 14,828 in successful primary vaccinations in these towns, and the proportion of persons successfully vaccinated per 1,000 of population rose from 33·10 per 1,000 in 1898 to 37·97.

Punjab.

There was a satisfactory increase in the number of vaccinations in the Punjab, as compared with the preceding year. Altogether 943,074 operations were performed in 1899–1900, showing an increase of 102,206 on the figures of 1898–99. The success achieved is attributed to the work being done in a more systematic way, the vaccinators having worked in bodies instead of as isolated units as in the previous year. The primary vaccinations numbered 744,917 with a percentage of success of 94·68. The most notable increase was in the Hissar district (31,959) which was due to the people being collected in famine camps. Only in eight districts out of 31 was there a decrease. Kangra is the best vaccinated district in the province and was practically free from small-pox during the year. On the other hand Peshawar, the least vaccinated district, had a severe attack, 2,288 deaths having been registered from the disease. In this district the people are reported to be averse to vaccination and inoculation is common. The number of successful cases among children under one year of age rose from 493,085 or 59·9 per cent. of the births, calculated at 40 per 1,000 of population, to 547,113 or 66·5 per cent. The provincial ratio of persons successfully vaccinated per 1,000 of the total population was 39·92, against 35·41 in the previous year. At the end of the year the Vaccination Act was in force in 22 towns and 11 cantonments.

Burma.

With a small increase in the number of vaccinators employed in the province of Burma an almost proportionate increase in the number of persons vaccinated resulted. The total number of persons vaccinated was 503,514, as compared with 480,657 in the previous year. Out of 463,605 primary cases, 94·8 per cent. were successful, a ratio identically the same as in the previous year. The number of infants protected was 130,822, equal to 40·14 per cent. of the births, estimated at 40 per 1,000 of the population. The returns for the Rangoon municipality were again very unsatisfactory. The number of primary vaccinations, fell from 5,516 to 2,457 and re-vaccinations from 4,938 to 2,899 ; while only 1,119 children under one year of age were successively vaccinated out of a total of 3,164 births. The Act for the compulsory vaccination of children is in force in all the municipalities of the province and with a view to further provide for compulsory vaccination in the province the Burma Vaccination Law Amendment Act was passed during the year. This Act empowers Superintendents of Vaccination in Rangoon Municipality, and in other municipalities to which the Act may be extended, to require unprotected persons to be vaccinated, and provides also for the compulsory vaccination of inmates of lodging houses or coolie barracks. These powers, the Sanitary Commissioner with the Government of India observes, "should avail for the protection of the coolie immigrants in Rangoon, a class very liable to harbour and spread small-pox, the compulsory vaccination of whom was discontinued in August, 1896."

Central Provinces.

On the whole good progress was made in vaccination work in the Central Provinces in 1899–1900. All but two of the 18 districts shared in the increase and "the figures" the Sanitary Commissioner remarks, "go to show that irrespective of the widespread scarcity and distress which prevailed among the general population during the last season, and the fact that a portion of the vaccination establishment was employed on famine, cholera, and

plague duty for a considerable period during the season, excellent work has been done by vaccinators." There were 509,323 persons vaccinated during the year, showing an increase of 60,073 on the number of the previous year. Primary vaccinations rose from 383,633 to 456,857 and the percentage of success from 96·33 to 96·82. The ratio of successful vaccinations in the year to the total population was 37·92 per 1,000, as compared with 31·70 in 1898–99. In the protection of infants there was an increase of 76,449, the number vaccinated under one year of age during the year having risen from 230,220 to 306,669, being equal to 60·18 per cent. of the births estimated at 40 per 1,000 of population. Animal lymph was used in the bulk of the vaccinations, and worked very successfully, and there is now little prejudice against its use in the province. Arm-to-arm vaccination is practised in very few places. With the lymph obtained from calves, 276,137 children were vaccinated during the year, and of these 264,099 were successful. The use of glycerinated lymph was attended with more satisfactory results than in the previous year, the percentage of success attained being 86·27 against 72·69.

Assam.

During the year 1899–1900 272,265 vaccinations were performed by all agencies in the province of Assam, being an increase of 13,360 on the previous year's work. The increase was not shared by all districts, five having recorded a decrease, chief among them being Kamrup. The increase was greatest in Sylhet, where the number rose from 72,292 to 84,359. Of the total operations 255,131 were primary cases, and of these 98·50 per cent. were reported as successful; this high average was attributed to the consistently excellent quality of the Shillong lymph. The Compulsory Vaccination Act continued in force during the year in the same 11 towns as in the previous year, but the number of vaccinations again fell. The number of infants successfully vaccinated was 61,793, representing only 27·02 per cent. of the births, estimated at 40 per 1,000 of the population, and the proportion of the population successfully vaccinated in the year was 46·62 per 1,000. Arm-to-arm vaccination has been abandoned throughout the province, the practice of inoculation is said to be dying out, "and no epidemic of small-pox could be traced to a survival of this custom."

Madras.

The total number of vaccinations performed in the Madras Presidency during 1899–1900 was 1,159,409, being an increase of 41,416 on the operations of the previous year, the increase being mainly attributable to a steady subsidence of the plague inoculation scare which caused the large fall in the previous year. Of the total, 1,096,821 were primary cases, of which 91·8 per cent. were successful, against 89·5 per cent. in 1898–99. The number of children under one year of age successfully vaccinated rose from 282,969 to 324,241, which represented only 22·74 per cent. of the estimated births. Vaccination is compulsory in all municipalities, and the number of operations performed by municipal vaccinators rose from 118,140 to 120,442. In the town of Madras the number of operations performed was 24,959, a decrease of 3,227 on the previous year, which was chiefly due to small-pox being less prevalent. Of the 21 districts, seven recorded a decrease of work, the most marked cases being those of Vizagapatam (16,738), Ganjam (5,065), Trichinopoly (4,838), and Coimbatore (4,629). The decrease in Vizagapatam is to be regretted, as the largest increase occurred in this district in the previous year. Among the districts showing the largest increase, Godavari came first with 17,819, followed by North Arcot 11,302, Tanjore 7,724, Salem 7,500, Tinnevelli 7,290, and Kistna 7,088. All the operations except one were performed solely with animal lymph, and the best results were obtained, as usual, from calf-to-arm vaccination, with a percentage of success of 97·3.

Bombay.

There was a considerable increase in the number vaccinated in the Bombay Presidency in 1899–1900 as compared with the previous year, though the figures were still below those recorded during each of the three years preceding 1898–99. Omitting the statistics of five Native States which are not under the supervision of the Vaccination Department, the out-turn of vaccination work in the Presidency rose from 669,652 operations in 1898–99 to 768,671. The total primary cases rose from 621,310 to 679,467, the percentages of success being respectively 92·84 and 92·60. The substitution of animal for human lymph continued to increase in the Presidency. In the City of Bombay vaccination with animal lymph has been in use for many years past. Of the 629,744 primary successful cases, nearly 81 per cent. were infants under one year of age. Reckoning the births at 40 per 1,000 of population, 56·30 per cent. were protected from small-pox. Inoculation was not practised anywhere in the Presidency during the year, and no instances were reported of any disease having been communicated through vaccination. The protection afforded to the population by the year's operations was in the ratio of 29·49 per 1,000.

Berar.

Considerable progress was made in vaccination work in Berar during 1899–1900, the number of persons vaccinated having risen from 132,903 in the previous year to 175,901, which is the highest number ever recorded in the province. The primary vaccinations rose from 94,032 to 120,772 ; but the percentage of success fell from 97·1 to 95·8. Of the total number of successful primary operations, 96,180 were performed on infants under one year of age ; estimating the births at 40 per 1,000 of population, 83·0 per cent. were protected against small-pox, and the proportion of population protected by vaccination rose from 34·6 in the previous year to 43·2. The increase in primary vaccinations was spread over all the districts. The large increase in primary work was due to the increased birth-rate, which reached 50 per 1,000 ; to the famine, bringing an influx of unvaccinated from across the Moglai border ; and to the vaccinators being able to get at children on famine relief works more readily. The Sanitary Commissioner continues his statement showing the efficacy of vaccination in checking small-pox mortality in Berar ; the ratio of successful vaccinations per 1,000 of population has risen from 8·92, the mean of five years 1868–69 to 1872–73, to 33·6, the mean of five years ending 1897–98 ; the mortality from small-pox for the same periods has declined from 2·02 to 0·19 per 1,000. In 1898–99 and 1899–1900 the ratios of successful vaccinations per 1,000 of population were 34·6 and 43·2, and the death-rate from small-pox 0·2 and 0·1 per 1,000. The Vaccination Act is now in force in all the municipal towns.

LIBRARY OF THE BOMBAY BRANCH OF THE ROYAL ASIATIC SOCIETY

VI.—MEDICAL INSTITUTIONS.

Civil Hospitals and Dispensaries.

The following comparative statement shows the number of hospitals and dispensaries open in the several provinces of India during 1899 and the previous year, and the number of patients under treatment :—

Provinces, &c.		Number of Institutions.	Number of In-door Patients.	Number of Out-door Patients.	Total Number of Patients.
Bengal	1898	487	42,086	2,837,759	2,879,845
	1899	513	47,897	3,243,346	3,291,243
Calcutta and Howrah	1898	15	23,732	187,518	211,250
	1899	15	24,146	219,302	243,448
North-Western Provinces and Oudh	1898	369	55,589	3,801,255	3,856,844
	1899	374	59,643	3,939,022	3,998,665

TOTAL	1898	2,342	334,883	19,066,756	19,401,639
	1899	2,472	355,769	20,238,917	20,594,686

The total number of dispensaries at work during 1899 in Bengal, exclusive of the medical institutions at Calcutta, was 513, an increase of 26 on the number of the preceding year. At these there were 3,291,243 patients under treatment, 47,897 being in-door and 3,243,346 out-door patients, against 42,086 and 2,837,759 respectively in the previous year. This shows a total increase of 411,398. "In view of the fact," the Local Government observe, "that the general mortality figure of the year 1899, though higher than that recorded in 1898, was considerably lower than in any of the four preceding years, this increase can only be attributed to the growing popularity of dispensaries." The attendance of in-patients has not yet returned to the position it held previous to the plague scare, but the number of out-patients is by far the largest ever recorded. Bengal.

There was again a satisfactory increase in the number both of women and children patients. The increase among women amounted to 55,446, the number having risen from 462,412 to 517,858. The proportion of women to men was, however, about the same as in the previous year, viz., 17·84 against 17·81 per cent. Of the diseases under treatment at the

dispensaries, malarial fevers, skin diseases, and dysentery and diarrhœa were responsible, as usual, for the largest number of cases. From malarial fever there were 623,173 cases, equal to nearly 19 per cent. of the total number of patients, against 527,695 in 1898 ; from skin diseases the number of cases rose from 402,890 to 501,830 ; from dysentery and diarrhœa there were 168,060 cases, against 154,117 in 1898, and "the fact that this increase is nearly four times that of the general mortality under these heads is a special testimony to the growing popularity of the dispensaries." From cholera the number of patients rose from 6,425 to 10,638. Cases of venereal diseases rose from 77,603 to 81,602. The number of deaths among in-door patients rose from 4,718 or 112·0 per 1,000 of total treated in 1898 to 5,559 or 116·0 in 1899. Great attention is paid in these institutions to surgery, and during the year 145,379 operations were performed, against 137,123 in 1898, and of these 230 terminated fatally. Among the more important operations there were 2,682 cases of extraction of the lens.

The following statement shows the number of in-door and out-door patients treated in the several hospitals and dispensaries in Calcutta and Howrah during 1899 and the previous year :—

Name of Institution.	1899.				1898.			
	In-door Patients.	Out-door Patients.	Total Number of Patients.	Died per 1,000 of In-door Patients treated.	In-door Patients.	Out-door Patients.	Total Number of Patients.	Died per 1,000 of In-door Patients treated.
Medical College Hospital	4,482	34,338	38,820	156·0	4,667	28,386	33,053	109·2

Grand Total	24,146	219,302	243,448	143·2	23,732	187,518	211,250	129·0

The figures for 1899 show an increase of 31,784 in out-door patients, and of 414 in in-door patients. The death-rate for all the hospitals was 143·2 per 1,000 of the total in-patients, against 129·0 in the previous year. Cholera patients rose from 227 to 355, and the fatal cases from 122 to 227. The increase was most marked in the Campbell Hospital, where 136 cases were treated against 89 in the previous year. Small-pox was slightly more prevalent in Calcutta than in the previous year, and the cases admitted to hospital rose from 36 to 42. Dysentery patients rose from 5,571 to 6,404. The number of patients treated for diarrhœa also rose from 6,244 to 6,673 ; malarial fever was responsible for 46,131 patients against 37,276. Plague cases treated rose from 135 to 229, and the deaths from 116 to 198. Venereal diseases show an increase of 609 patients, the number treated having risen from 10,550 in the previous year to 11,159. Surgical operations increased from 21,610 to 25,109, and death ensued in 154 cases in both years.

North-Western Provinces and Oudh.

During 1899 there were 374 hospitals and dispensaries at work in the North-Western Provinces and Oudh, or 5 more than in the previous year. The number of patients who received medical aid was 3,998,665 against 3,856,844, in 1898. There was thus an increase in 1899 of 141,821. The number of in-patients rose from 55,589 to 59,643. Of the total number, 51·6 per cent. were men, 22·9 per cent. were women, and 25·5 per cent.

were children, the last two showing a small increase on the figures of the previous year. Among the in-door patients there were 2,865 deaths, against 2,801, but the death-rate fell from 50·3 to 48·0 per 1,000. Of the diseases for which the patients were treated 661,153 were suffering from malarial fevers, a decrease of 30,826 on the number of 1898; 520 cases of cholera were treated in the dispensaries, against 368, and cases of diseases of the eye rose from 318,522 to 365,369. From venereal diseases there were 82,884 patients, against 95,165 in the previous year. The number of surgical cases rose from 175,708 to 180,190, of which 149,499 resulted in cure and 390 were fatal. Of the total operations 5,778 were for cataract, of which nearly 84 per cent. were successful, as compared with 5,648 operations and a percentage of success of 83 in 1898.

Punjab.

The number of dispensaries at work in the Punjab during 1899 was 272 or five more than in the previous year. At these, 3,154,277 patients were under treatment, being an increase of 128,888 on the number of 1898. The attendance of in-door patients was greater than in the previous year by 2,899, the number having risen from 49,068 to 51,967. This improvement is satisfactory, as there had been an annual decrease in the number of in-patients since 1894, for which year the number was 56,254; and as the same circumstances which had tended to operate against attendance in previous years existed in 1899, the increase may be attributed to the popularity of the institutions. Of the diseases for which patients sought relief there were only 219 cases of cholera, though this is a large increase on three in 1898. Cases of malarial fever fell from 463,223 to 381,465. Diseases of the eye showed an increase of 66,974 cases, the number treated in 1899 being 448,382, against 381,408. From venereal diseases there were 30,002 cases under treatment, an increase of 1,363 on the previous year's figures. Among the in-patients there were 2,292 deaths during the year, being in the ratio of 44·1 per 1,000 of the number treated, against a death-rate of 42·0 in 1898. The number of surgical operations amounted to 170,051, which, compared with the previous year, shows a falling off; but there was really an increase, as, in the year under notice, orders were issued directing that certain operations were in future to be excluded from dispensary returns. Of these no less than 13,410 were, it is stated, included in the returns for 1898, and if this number is deducted the number of operations is reduced to 157,399 or 12,652 less than in 1899. Of the 170,051 operations, 162,394 were cured and 282 died. There were 5,321 cataract operations, and of these 85·7 per cent. resulted in cure.

Burma.

The number of dispensaries existing in Burma at the end of 1899 was 110, or five more than in the previous year. At these, 818,039 patients attended, as compared with 799,521 in 1898. The number of in-door patients rose from 34,091 to 34,749, of whom 25,591 were cured, and 2,611 or 75 per 1,000 died, against 2,487 deaths or 73 per 1,000 in the previous year. Nearly 58 per cent. of the patients treated were Burmese. Malarial fevers, as usual, headed the list of maladies under treatment, the number of cases being 125,373, against 127,177 in the previous year. Cholera was more prevalent than in 1898, and the number of cases rose from 342 to 581. Cases of venereal disease fell from 28,966 in 1898 to 24,627. Surgical work showed an increase of 664 operations, the number performed during the year having risen from 16,490 to 17,154; though showing a slight improvement, the result is not considered satisfactory "in a province like Burma, where there is practically an unlimited field for the expansion of surgery." The number of patients cured, after being subject to operation, was 16,460 and 80 died.

Central Provinces.

The number of hospitals and dispensaries at work in the Central Provinces during 1899 was 127, or 2 more than in the previous year. The total number of patients fell from 1,547,918 to 1,531,642. The decrease, however, extended only to out-door patients, the in-door patients having risen from 11,179 to 11,434. The diminished out-door attendance is attributed by the Administrative Medical Officer to the large number of people who, during the last three months of the year, resorted to famine relief camps, and whose sick (40,324) were treated in the special hospitals attached thereto. Among the in-patients there were 892 deaths or 78·0 per 1,000 of total treated, against 1,042 or 93·2 in 1898. As regards the different kinds of diseases, the most remarkable feature was the further large decrease of cases of malarial fevers by 36,544. On the other hand there was an increase of 3,699 cases of dysentery and diarrhœa. From venereal diseases there was a decrease of 1,134 cases. There were 34,884 surgical operations performed, against 39,552 in 1898. Of these, 33,146 resulted in cure and 69 in death. Operations for cataract declined from 1,026 in 1898 to 953.

Assam.

In the province of Assam there were 115 dispensaries at work during the year, or seven more than in the previous year. The total number of patients treated was 623,803,

against 610,267 in 1898. The increase was entirely in out-door patients, and apparent only, " being almost wholly due to the seven new dispensaries opened during the year." The in-patients declined from 6,977 to 6,217, and of these 3,600 were discharged cured, 476 relieved, 932 discharged otherwise, and 942 died, the latter representing 151·5 per 1,000 of the total in-patients, against a ratio of 160·7 in 1898. The decline in in-door attendance is attributed to the unusual healthiness of the year, cholera being much less prevalent, as were also kala-azar and malarial fevers. Of the 942 deaths 387 were due to pauperism and starvation amongst waifs and strays from the railway and tea estates. Of the total attendance, only 14 per cent. were women. This is, however, an increase on the previous year's figures, and as arrangements have now been made at all dispensaries for women to be received in a separate apartment with a separate entrance, it is expected that their attendance will go on increasing yearly. Of the total number of persons who received medical aid, malarial fever accounted for 142,736 cases, including 3,736 suffering from kala-azar, against 5,572 from this disease in the previous year; dysentery and diarrhœa 29,970, and diseases of the digestive system 32,640. Cholera patients declined from 2,972 in 1898 to 1,449. With the exception of a rather severe local outbreak at Mullapara in Sylhet, resulting in 470 cases, most of the cholera cases occurred in the Goalpara district. Of surgical cases there were 15,066, of which 14,467 were cured and 39 were fatal.

Madras. Exclusive of the hospitals in the Presidency town there were 523 civil hospitals and dispensaries working in Madras at the close of 1899, or 51 more than in 1898, but several were closed for broken periods during the year. There were 4,226,308 patients under treatment, as compared with 4,067,111 in 1898. There was thus an increase of 159,197. Of the 46,510 in-door patients, 30,399 were returned as having been cured under treatment, 8,505 as relieved, and 3,478 as otherwise discharged. The deaths numbered 2,502, representing a ratio of 54·2 per 1,000 of the total in-patients, against 71·1 in the previous year. Ulcers and diseases of the skin, malarial fevers, diseases of the eye, diseases of the digestive system, rheumatic affections, dysentery, and worms were the most common diseases under treatment during the year. Cholera was much less prevalent in the Presidency than in the previous year, and the cases under treatment in the various hospitals and dispensaries fell from 9,783 to 3,234. From venereal diseases there were 78,002 cases, against 83,328 in 1898. The surgical operations fell from 147,001 in 1898 to 121,261. Of these, 115,401 were cured and 173 were fatal.

The number of medical institutions in Madras town remained the same as in 1898, but the number of sick treated rose from 202,464 to 211,929. The in-patients fell from 18,584 to 16,674, and amongst them 8,402 cases were recorded to have been cured or perfectly recovered, 3,254 were relieved, 3,035 discharged otherwise, and 1,098 or 65·9 per 1,000 died, against a rate of mortality in 1898 of 80·2. The decrease in mortality was chiefly under small-pox, measles, fevers, and cholera. Of the several diseases for which the patients were treated, malarial fever, diseases of the digestive system, skin, and respiratory system were, as usual, the most common. From cholera there were only 28 cases, against 505 in the previous year, from dysentery and diarrhœa 7,797, and from venereal diseases 3,804. Fewer surgical operations were performed, the number having declined from 28,725 in 1898 to 16,243. The results showed that 12,373 cases were cured, 2,646 relieved, and 114 were fatal.

At the Madras Voluntary Venereal Hospital, which is included in the above hospitals in the city, there were 512 female patients treated during 1899, a decrease of 126 on the number of the previous year.

ombay. Excluding the 11 medical institutions in the City of Bombay, there were 343 hospitals and dispensaries working in the Presidency at the end of 1899. At these, 2,029,422 patients were under treatment, of whom 32,831 were in-door and 1,996,591 out-door patients, against 29,904 and 1,721,332 respectively in 1898. The attendance of patients was rapidly returning to the normal; for whereas the total treated in the year 1897 was 639,265 less than that of 1895, the figures for the year under report are only 352,647 short of those of the year 1895, which preceded the appearance of plague. Malarial fevers, as usual, constituted by far the largest number of cases (347,747), and showed an increase of 45,642 on the figures of the previous year. Next to fever, eye and skin diseases and worms were the most common ailments. The only important disease which showed a decrease was small-pox, the number of cases having fallen from 438 in 1898 to 194; cholera cases rose from 606 to 630; dysentery cases were also more numerous; and patients suffering from venereal affections rose from 27,217 in 1898 to 32,801 in 1899.

Of the in-door patients 23,300 were cured, 2,258 relieved, 1,894 discharged otherwise, and 3,810 died, the ratio of deaths to total treated being 116 per 1,000, against 103 in the preceding year. The total number of patients operated on was 72,518, as compared with 83,255 in 1898, and of these 62,243 were cured and 213 died. The large decrease in the number of operations is owing to the omission of certain comparatively trivial procedures as desired by the Government of India; but on the whole the more important operations slightly exceeded the number of the previous year.

The total number of patients treated at the 11 civil medical institutions working in the town of Bombay during 1899 showed an increase of 17,440, the figures being 100,459, against 83,019, in the previous year. The in-patients increased in number from 16,564 to 18,071, and of these 10,801 were cured, 3,016 relieved, 926 otherwise discharged, and 2,335 died, the deaths being in the ratio of 129 per 1,000 of the in-patients, against 125 per 1,000 in 1898. As usual, local injuries, malarial fevers, eye diseases, and skin diseases were responsible for the majority of the cases. Venereal diseases contributed 3,626 cases, against 3,771. There were no cases of cholera under treatment; but dysentery cases rose from 1,040 to 1,449, and diarrhœa cases from 2,830 to 3,805. The total number of patients operated on was 10,401, and of these 6,519 were cured, 185 relieved, 67 discharged otherwise, and 192 died.

Berar.

There were 48 medical institutions at work in Berar during 1899, the same as in the two previous years. Of these, eight are hospitals wholly maintained by the State. The total number of patients under treatment was 331,698, against 325,379 in 1898. In in-patients there was an increase of 522, and in out-door patients of 5,797. Of the in-patients, 3,740 were cured and 299 died, which gives a death-rate of 65 per 1,000. Malarial fevers continued to head the list of diseases from which relief was sought, nearly a fifth of the total patients were treated under this head; diseases of the eye and diseases of the digestive system came next in order. The number of surgical operations was 11,104, against 11,704 in 1898. Of these, 10,907 were cured and 34 were fatal. The decline in surgical work was attributed to the exclusion from the list, under instructions of the Director-General, Indian Medical Service, of certain minor surgical procedures.

The work of the Lady Dufferin Hospital for women and children at Amraoti showed some improvement during the year under report. The number of in-door patients rose from 143 in 1898 to 151, and the out-door patients from 5,913 to 6,847.

Lunatic Asylums.

Bengal.

At the five asylums in Bengal (viz., Dullunda, Dacca, Patna, Cuttack, and Berhampore) 1,131 lunatics, including 220 fresh admissions and re-admissions, were under treatment in 1899, being a decrease of 48 on the number of the previous year. In the course of the year under notice 110 patients were discharged as cured, and 27 as improved or otherwise, and 87 died. Compared with the figures of 1898, the number discharged was more by 56, and the mortality by 14. At the end of the year there were 889 persons still under detention, or 22 less than at the close of 1898. There was a marked improvement in the health of the inmates of the asylum, the average daily number of sick being 86, against 105. The death-rate was, however, higher, being 96·3, against 79·1 per 1,000 of average strength. The cause of insanity was traceable only in 102 of the 220 fresh admissions, and 44 of these were ascribed to ganja smoking. The results of the working of dairy farms at the asylums were fairly satisfactory. At Dullunda there was a profit of £55 as compared with £43 in the previous year. At Dacca the dairy was less profitable than in the previous year. The dairy farm at Berhampore also worked with better results and showed a small profit.

In the Bhowanipur Asylum, containing European and Eurasian patients only, the inmates during 1899 numbered 54, or one more than in the previous year. Of this number 35 were under detention at the beginning of the year, and 19 were subsequently admitted. In the course of the year 5 patients were discharged cured, 7 were transferred to the care of friends, 4 died and one was despatched to Europe as still insane, leaving 37 under confinement at the close of the year. As regards the health of the patients during the year, there were only 6 admissions to hospital, against 5 in the previous year, and 4 deaths, against 2.

North-Western Provinces and Oudh.

The inmates of the four lunatic asylums (Agra, Bareilly, Benares, and Lucknow) in the North-Western Provinces and Oudh in 1899 numbered 1,349, including 319 fresh admissions during the year, against 1,290 in 1898. Before the close of the year 162 patients were

discharged, of whom 124 were reported as cured, 38 were made over to friends, 72 died, and 2 escaped, leaving 1,115 under treatment at the end of the year. The health of the asylum population showed improvement, the total mortality fell from 87 in 1898 to 72 in 1899, there being a marked decrease in all except Agra. The scheme for a large central institution at Agra, under the charge of a whole-time Superintendent, mentioned last year, remained for a time in abeyance pending the decision of the question whether the site of the asylum would be wanted for a combined railway station. That question having been decided in the negative the work has been resumed.

Punjab. The total number of lunatics in the Lahore and Delhi lunatic asylums in the Punjab during 1899 was 607, including 183 fresh admissions, against 558 in 1898. Both asylums are reported to have been overcrowded throughout the year, and the number remaining at its close is the highest yet recorded. The overcrowding is, however, fortunately of no moment now as the new Central Lunatic Asylum for the whole of the province at Lahore has been completed, and the patients from both the old asylums have been moved into it. At the end of the year the number was reduced to 457 by the discharge of 114 patients, 65 as cured, 27 made over to friends, and 15 otherwise discharged, and 35 deaths. As regards the health of the inmates of the asylums, the number of admissions to hospital during the year was 416. In Lahore the cases fell from 423 in 1898 to 327, and the number of deaths was 27 or 90·3 per 1,000 of average strength, practically the same as in 1898 when the mortality was 26 or 90·8 per 1,000. In the Delhi Asylum the admissions into hospital rose from 47 in the previous year to 89, but the deaths fell from 14 or 107·1 per 1,000, to 8 or 57·1. No special diseases were present in any unusual degree except pneumonia, from which there were 22 cases at Lahore or one more than in 1898. In the Delhi Asylum also, pneumonia cases rose from 4 to 7. Of the total number of admissions in more than one half (96) the cause of insanity was unknown.

Burma. The Rangoon Asylum is the only one in the province of Burma, and has accommodation for 404 insanes. During 1899 there were 462 patients in the asylum, including 117 fresh admissions, and the total was reduced at the close of the year to 365 by the discharge of 67 patients for different causes, and the death of 30. The general health of the inmates appears to have been good; the admissions to hospital rose from 153 to 173, and the deaths fell from 41 or 119·2 per 1,000 of average strength to 30 or 83·3. More than two-thirds (21) of the inmates who died were in bad or indifferent health at the time of admission to the asylum. The Inspector-General reports that "out of 117 admissions during the year a cause of insanity was assigned to 57 only or 49 per cent. Although every case where the cause of insanity was unknown was referred back for further information, and considerable pains taken to ascertain the previous history and habits of the patients, yet in most instances failure was the result."

Central Provinces. In the two asylums of the Central Provinces (Nagpur and Jubbulpore) there were 395 lunatics under treatment during 1899, an increase of 11 on the number in 1898. In the course of the year 41 patients were discharged as cured or otherwise, and 14 died, leaving 340 still under treatment at the end of the year. There was a satisfactory improvement in the health of both asylums. The admissions to hospital at Nagpur fell from 205 to 69, and at Jubbulpore from 100 to 93. The decrease at Nagpur was due mainly to the fall in cases of influenza from 129 in 1898 to 1 in 1899. Of the total 14 deaths, Nagpur recorded 11, being in the ratio of 63·6 per 1,000 of average strength, against 24 or 104·6 in 1898. Seven of the 11 deaths in this asylum were due to dysentery and debility. At Jubbulpore there were 3 deaths, being in the ratio of 19·4 per 1,000, against 7 or 45·8 in 1898. Of the 69 admissions during the year, 23 were returned as due to unknown causes.

Assam. There is only one lunatic asylum in the province of Assam, and this is situated in Tezpur. The total number of lunatics under treatment in the asylum during 1899 was 147, the same number as in the previous year. Of these, 22 were fresh admissions. At the close of the year the patients in the asylum were reduced to 119, 18 of the total number having been discharged, 1 escaped, and 9 died. The health of the inmates was satisfactory. Among the 147 inmates 57 were admitted to hospital, as compared with 86 in 1898. The number of deaths was, however, more by four than in 1898, and the death-rate rose from 40·3 per 1,000 of average strength to 71·1. It is explained that three of the deaths were non-preventible, and deducting these there remain only six deaths out of a daily average of 126·47, against five in 1898 out of a daily average of 123·98. The causes of insanity were unknown in 11 of the 22 new admissions.

Madras. At the commencement of 1899 there were 577 patients under treatment in the three lunatic asylums (Madras, Vizagapatam, and Calicut) of the Madras Presidency. During the year 151 fresh cases were admitted, bringing the total population up to 728, or 14 more than the number in the preceding year. In the course of 1899 there were 115 cases of discharge, and of these 101 were cured or improved. The accommodation was ample, and there was no overcrowding in any of the asylums during the year. On the whole there was more sickness among the patients than in the previous year, but all three asylums were free from epidemics during 1899. The daily average sick rose from 75 to 81, and the deaths from 46 or 79·3 per 1,000 of average daily strength, to 59 or 101·1. Of the total 59 deaths the Madras Asylum contributed 51, giving a death-rate of 117·7 per 1,000 on an average strength of 433, against a ratio of 75·2 in 1898. The death-rates of the other two asylums, Vizagapatam and Calicut, were 28·0 and 77·2 per 1,000 respectively, against 82·7 and 97·2 in the previous year. The increase in the mortality in the Madras Asylum was mainly due to the bad state of health of new admissions, 18 being so admitted, and of these three died within one month and seven within three months of admission. Of the 151 fresh admissions, the causes of insanity were unknown in 53 or 35·10 per cent.

Bombay. The total population of the six lunatic asylums of the Bombay Presidency (Colaba, Ratnagiri, Poona, Dharwar, Ahmedabad, and Sir Cowasji Jehangir, Hyderabad) was 1,114, including 303 fresh admissions, against 1,043 in 1898. In the course of the year 224 patients were discharged, 89 of them as cured, and 86 died, leaving 804 under treatment at the close of the year. There was slightly less sickness in the asylums than in 1898, the daily average sick having decreased from 41 to 37, but the deaths rose from 55 or 69·9 per 1,000 of average strength, to 86 or 108·2. Of the 86 deaths, 20 were due to dysentery, 18 to phthisis, and 8 to Bright's disease. The Colaba Asylum recorded the highest mortality of 53 deaths, or 168·2 per 1,000 of average strength, which was nearly double the rate recorded in the previous year, viz., 86·7.

Medical Schools.

Bengal. The number of medical schools open in Bengal during 1899–1900 was nine, or two less than in the previous year. The Medical College, Calcutta, and four of the medical schools are maintained by Government, the rest are unaided. The college is affiliated to the University, and prepares candidates for its various medical degrees. The four Government medical schools train pupils as Civil Hospital Assistants, and the four unaided schools follow their own standards for private practice. The total number of pupils attending the various medical schools in the province was 1,582, as compared with 1,709 in the previous year.

The students of the medical college are required to undergo three University examinations during their five years' study, viz., the Preliminary Scientific examination at the end of the second year, the first L.M.S. or the first M.B. examination at the end of the third year, and the second L.M.S. or second M.B. examination at the end of the fifth year. The number of students at the College at the beginning of the session in 1899–1900 was 591 (including 16 women), against 576 in the preceding year. As regards the examinations, 161 candidates were successful out of a total of 431 (including one woman), the successes being at the rate of 37·35 per cent., as compared with 48·76 per cent. in 1898–99. Of the 161 successful candidates, only 11 out of 81 passed the Preliminary Scientific L.M.S. examination, 70 (including one woman) passed the first, and 35 the second L.M.S. examinations; 22 passed the Preliminary Scientific M.B. examination; three passed the first and two the second M.B. examinations.

The Campbell Medical School had 291 pupils (including 27 women) on its rolls at the end of the session. Of this number 19 males and 3 women passed the final examination for the diploma.

At the Dacca Medical School there were 191 pupils on the rolls (including 6 women). Nineteen students, all males, passed the final examination.

The Temple Medical School, Patna, had 165 students (including 5 women) on its rolls at the end of the session. At the final examination 23 candidates passed.

At the Cuttack Medical School the number of pupils at the close of the session was 112 (including 9 women). Ten candidates out of 17 passed the final examination.

North-Western Provinces and Oudh. The number of pupils attending the Agra Medical School in 1899–1900 was 244 (including 56 women), or 14 more than in the preceding year. The work of the students (male and female) is reported to have been diligent and satisfactory. The results of the final

examination of male students show that 43 out of 47 candidates passed. Fifteen of the 17 military students in the first or final class passed, and 28 of the 30 civil students passed. Of the students in Class II., comprising second-year military and third-year civil, private, and Rajputana pupils, all the 11 military pupils and 33 out of the remaining 47 pupils passed the first half professional examination.

As regards the examination of women students, the whole of the first-class, viz. nine, obtained their diplomas, and 17 out of 30 passed their class examinations, as compared with 14 out of 27 in the preceding year.

Punjab. The average attendance at the Lahore Medical College and School was less by 14 as compared with that of 1898–99, viz., 429 against 443. Of these 191 (including 5 women) were in the College, and 238 (including 2 women) in the Medical School. The results of the year's examinations show that for the Preliminary Scientific Examination, 19 out of 26 candidates passed. In the first L.M.S. and M.B. examinations, only 18 candidates out of 50 passed, against 32 out of 66 in the previous year, and in the second L.M.S. and M.B. examinations 28 out of 50 passed, against 21 out of 52 ; in all 65 out of 126, or 51 per cent. were successful. In the final examination for the hospital assistant diploma 67 passed out of 71, or 94 per cent.

The Medical School for Christian women continues to make progress and to do good work at Ludhiana. The object of the institution is "to provide a thorough medical "training, under fully qualified Christian women, for those Christian women and girls "who wish to prepare themselves for medical mission work." At the end of 1899 there were 58 students on the rolls, or 32 more than in the previous year ; of these 21 belonged to the Medical classes, four to the Compounders' classes, 17 to the Dais' classes, and the rest to the Nurses classes.

Madras. The number of students at the Madras Medical College (including the School Department) during 1899–1900 was 441, of whom 31 were women students. In the Hospital Assistant Department, consisting of 180 pupils, 70 appeared for the final examination, and 50 passed. The results of the several University examinations in medicine were again satisfactory, 44 having passed out of 66 candidates entered, against 26 out of 57 in 1898. In the College Department there were 65 regular students, including one woman student, reading for the M.B. and C.M. degree, 16 reading for the L.M.S. degree, and 14 casual students.

The Board Medical School at Nellore having been closed, the only other medical school at work during the year was the Prince of Wales' Medical School, Tanjore. At this there were 36 pupils on the rolls, all of whom were being prepared for the Hospital Assistants' Certificate. Fourteen candidates appeared for the final examination and 9 passed.

Bombay. The attendance at the Grant Medical College, Bombay, rose from 340 in 1898–99 to 368 (including 22 women) in 1899–1900. For the first University examination in medicine 149 candidates presented themselves, of whom only 87 qualified ; and for the second examination in medicine only 32 passed out of 89 candidates. For the final examination for the degree of L.M.S there were 54 candidates, and of these only 14 passed, 3 qualifying in the first class and 11 in the second. There were 38 military medical pupils, and of this number 10 passed their final examination, and were promoted to the grade of military assistant surgeons.

The Government Medical Schools at Poona, Ahmedabad, and Hyderabad continued to work satisfactorily. The average number of students on the rolls was 224, and the results of the examinations were satisfactory.

VII.—SANITATION.

In Calcutta progress continued to be made in the improvement of bustees, or clusters of Native huts. In the matter of water supply there is, as last year, nothing to record but the ordinary progress of the existing system. The average daily consumption of filtered water was 20,681,822 gallons, equal to nearly 34 gallons per head of population for the town proper, and nearly 21 gallons for the suburban area. In the course of the year the distribution pipes were slightly extended, bringing the total length up to 315·64 miles. The total number of premises connected reached 28,953. A great advance was made during the year in increasing the supply of unfiltered water. The mileage of unfiltered water mains in the towns and added area rose from 130¼ miles to 155 miles. The consumption of unfiltered water was 9,687,500 gallons, or nearly double the quantity consumed in the previous year; the daily consumption per head of population was slightly over 21 gallons against 11 gallons in the previous year. Improvements in the sewage and storm water outfalls of the town and suburbs, and the provision of a system of sewers for the suburbs were in hand. Various reconstructions and improvements were made in the sewerage system which at the close of the year had a length of over 200 miles, and the number of premises connected with the system was 30,670, of which 502 connections were made during the year. The presence of plague in an epidemic form rendered necessary a large amount of disinfection work, and for this purpose a staff of five European doctors with a considerable number of inspectors, was retained. It is reported that the policy of relying entirely on disinfection was successful, and that practically all cases of plague were reported. **Bengal.**

The municipalities of the interior of Bengal spent nearly 45 per cent. of their income on sanitation as compared with nearly 46 per cent. expended in the previous year. In addition a further sum of £20,300 was contributed by private individuals for sanitary works. The most important work was the completion of a portion of the flushing scheme of the Patna municipality. The new water-works at Berhampore were opened during the year, and were reported to be most successful and much appreciated by the inhabitants. The towns in which drainage schemes have been carried out numbered six, exclusive of Calcutta, and nine towns have improved water-supply.

The Sanitary Board held three meetings during the year, and continued as usual to advise the Government and local bodies on the important sanitary projects of the year. Among these were schemes for the improvement of the water supply of Dacca and Bhagalpur, and drainage projects for Manicktolla, Siwan, Dinajpore and other places. A preliminary estimate of £12,250 was also given for a scheme for increasing the water-supply at Darjeeling, and a proposal to supply Patna with water was also under consideration.

In the North-Western Provinces and Oudh the municipalities expended 35 per cent. of their aggregate income on water supply, drainage and conservancy. Nine towns, Agra, Allahabad, Benares, Cawnpore, Lucknow, Meerut, Mussoorie, Dehra Dun, and Naini Tal, are now furnished with waterworks and pumping machinery; these towns contain about one-third of the municipal population of the province. At Agra the water supply arrangements were being repaired and improved during the year; in Benares the large sewerage works were in progress; in Cawnpore a new sewerage scheme was laid before the Sanitary Board; and in Naini Tal the new water supply was practically completed. Sanitary notebooks have been introduced in 22 districts. **North-Western Provinces and Oudh.**

The Sanitary Board met four times in the course of the year. Among the more important matters that engaged their attention was the analysis of the water from municipal waterworks. In nearly all cases the water was found to be pure; but the enteric microbe was detected in a sample of water from the Agra cantonment in time to prevent any ill results.

In the Punjab the municipal towns spent over 24 per cent. of their income on sanitation in the year 1899. Water supply or drainage works were either completed, in progress, or under consideration in fourteen of the most important towns. The water **Punjab.**

supply works at Simla were practically completed during the year, and work was begun on the Delhi extension scheme and other less important projects. Important works of this character were under consideration in Bhiwani and Dharmsala. Not much progress was made during the year with the construction of drainage works, and operations were suspended at Delhi owing to lack of funds. Several important projects were, however, under consideration, including a scheme for Umballa, estimated to cost nearly £7,000, and an extension scheme for Simla. Preliminary operations were in progress in connection with the Rawalpindi scheme, of which the estimated cost is £9,800. Private individuals also spent sums aggregating £5,100 on the construction of minor sanitary works during the year 1898–99. The system of village sanitary notebooks is in force in many villages, and is found to be of considerable value. Rewards are offered to village headmen who have shown conspicuous interest in the sanitation of their villages, and a few villages were recommended for such grants during the year.

The Sanitary Board met seven times during the year, and discussed several sanitary matters of more or less importance. The appointment of a Sanitary Engineer for the province was under the consideration of the Government.

Burma. No sanitary work of any importance was undertaken in Burma during the year. The municipalities spent £133,300, or nearly 34 per cent. of their income on water supply, drainage, and conservancy; these figures include the ordinary sanitary work of Rangoon, which cost £101,200, or 45 per cent. of the municipal income, but they do not include the large expenditure on the reclamation works. The recently appointed Sanitary Engineer submitted six water supply schemes, of which the following three were of importance:—Bassein, to cost £26,800, Minbu £6,700, Akyab £26,600. Progress was made with the water supply projects for Moulmein, Maymyo, and the Meiktila and Rangoon cantonments, and an important scheme for the improvement of the Rangoon water supply, to cost £70,000, was revised by the Engineer during the year. No large drainage scheme is at present in progress. Village sanitary notebooks are in general use, and by their aid permanent sanitary records are to be kept. In Rangoon £19,200 were spent on the reclamation of the eastern portion of the city, making the total so spent up to date £122,500. The Lanmadaw portion is still very insanitary, and reclamation work will, it is hoped, shortly be begun there. A scheme for the removal of rubbish in East Rangoon, put into operation during the year, gave good results. The drainage of the city is on the Shone system, and worked satisfactorily. Additional precautions were taken during the year to prevent a breakdown in the machinery. It has been decided to dispense with the Royal Lake as a reservoir for the water supply.

The Sanitary Board was practically non-existent during the year, owing chiefly to official changes and departures, but proposals for its reconstitution were under consideration.

Central Provinces. The municipalities in the Central Provinces expended over £27,000, or 40 per cent. of their income, on sanitation in the year 1899. The water supply works in Jubbulpore and Khandwa were advanced, and those in Wardha and Bhandara were completed; the drainage of the town of Jubbulpore was improved at considerable cost, and a project was under consideration to utilise the water from the outfall drain for the manuring of cultivated land in the neighbourhood of the town. The Harda water-works scheme was again in abeyance, owing to want of funds. Two new villages were brought under the Village Sanitation Act during the year.

Owing to famine, there was only one meeting of the Sanitary Board during the year, and to this cause also is referred the scanty progress in filling in the village inspection notebooks, which have been started in all districts. The famine was also the cause of the short results in respect of the sanitary maps which have been prepared with a view to the collection of vital and sanitary statistics; the introduction of this system has been postponed until the new census figures are available.

Assam. Excluding six towns which have no separate incomes of their own, the municipal authorities in Assam spent nearly 43 per cent. of their income on sanitation in the year 1899. No extensive sanitary work was undertaken during the year, but in almost all municipalities small sums were spent on improvements to the drainage and water supply systems. The sanitary improvements effected in rural tracts were chiefly in the direction of providing a purer water supply by the construction of masonry wells and the excavation of tanks at some of the larger villages; six tube wells were sunk in the Kamrup district. Sanitary inspection books were kept up in selected villages, but owing to a

lack of interest in sanitary matters on the part of the village officials the books are in many cases of little value.

No formal meeting of the Sanitary Board was held during the year, but the Government of India having invited attention to this matter, meetings of the Board have since taken place and will be continued in future.

In the Madras Presidency the district municipalities allotted 53 per cent., and the district boards 7 per cent., of their income for sanitary purposes. A large portion of this expenditure was on conservancy, but the allotment out of municipal incomes for water supply altogether amounted to £49,500 in addition to that of Madras city. The extension of the water-works at Conjeeveram and of pipe lines in Tanjore were completed in 1899, and the water supply scheme for Tirupati, which was estimated to cost £15,400, was also finished. Seven water-supply schemes were prepared and submitted; schemes for the water supply of Coonoor and Tuticorin, and for the extension of water-works at Trichinopoly and Cuddapah were sanctioned by Government. Besides these, drainage projects for the Ootacamund bazaar and Kumbakonam were under consideration. The advance noted in 1898 in respect of conservancy was checked by the financial uncertainty caused by the presence of plague. Village sanitary inspection report books were in general use in 19 out of the 22 districts of the Presidency. Madras.

In Madras city a sum of £32,000 was expended on sanitation during the year, the chief item being £27,000 on conservancy. The work of taking levels and framing estimates for the city drainage was begun during the year. The Mylapore drainage system, recently completed, worked satisfactorily, with the exception of the bursting of some cement pipes. An incinerator was completed and brought into use, and over 22,000 cartloads of rubbish were destroyed. The quantity of water supplied from the Red Hill Lake was about 5 per cent. greater than in the previous year; but the level of the lake was lower at the close of the year than at the beginning.

The Sanitary Board scrutinized plans and estimates for one provincial, 34 municipal, and 79 local fund works, of the estimated cost of £128,900. Proposals for 17 other schemes were also considered by the Board; and six new standard type designs of minor sanitary works were approved for issue.

In Bombay City the gravitation portion of the Mazagon sewage works was completed during the year, as were also the surface drainage works in the Kamatipura district. Progress was made with the supply of machinery, &c., for the Parel and other sewage districts, and other important drainage works were at various stages of progress. Owing to the deficient rainfall, the water in the lakes from which the city takes its supply was affected both in quantity and quality, but the supply was sufficient. The vexed question of surface water disposal and sub-soil drainage continued to engage the attention of the Corporation at close of the year. Mr. Santo Crimp, who was called in to advise on the subject, submitted his report, and steps were being taken to give effect to his recommendations. Bombay.

In the other municipalities of the Presidency over 49 per cent. of the income was allotted for sanitary purposes, and 10 per cent. by the local boards, though in neither case was the full allotment spent. The whole expenditure on sanitary purposes was £178,600. Of the municipal sanitary expenditure, 20 per cent. was spent on the improvement of water supply, 43 per cent. on conservancy, and the rest on improvement of town sites, markets, provision of tanks, &c. The large expenditure on plague precautions checked the prosecution of sanitary works; a drainage scheme at Ahmedabad, water-works at Hyderabad, and water supply and drainage projects at Poona, were under consideration; but until the pressure of plague and famine has passed away funds are not likely to be available for their execution. The Bombay Village Sanitation Act was introduced in five other villages during 1899, and was abolished in four, making a total of 300 villages now under its provisions. The Act provides for the establishment of a sanitary committee or a sanitary board, consisting of members chosen by the collector of the district or by the Local Government, to supervise sanitary matters. Village sanitary inspection books were in use in 3,225 villages.

The Sanitary Board gave advice concerning several projects, including the Poona drainage scheme and water supply scheme for the city, and the military proposals regarding the sanitation of the Kamatipura section of the Sadar bazaar at Poona.

The municipalities of Berar spent 48 per cent. and the district boards about 17 per cent. of their income on sanitary improvements in 1899. No new works of importance Berar.

were in progress during the year. In the municipalities of Karinja and Buldana expenditure on drainage schemes had been sanctioned, but operations were stopped by the famine. A drainage scheme for Ellichpur municipality has been under consideration. The District Sanitary Boards met once at each of the six headquarter stations. The sanitary survey of selected towns and large villages made fair progress, and the number of towns now surveyed is 37, and of villages 1,127, leaving two towns and 4,116 villages still to be surveyed. The suggestions made for improvements, as a result of the survey, caused the expenditure of £1,500 during the year by district boards, but in many cases they could not be put into effect owing to lack of funds.

India Office,
November, 1901.

ABSTRACTS

OF

SANITARY AND OTHER REPORTS

FOR

1899.

ABSTRACT OF THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1899.

(Surgeon-General Robert Harvey, M.D., C.B.)

European Troops.

Sickness and Mortality in 1899.—The health of the European army of India was again much better than in the preceding year, and only the invaliding rate was greater than the corresponding decennial ratio. The year on the whole was hot and dry with deficient rainfall. To these meteorological conditions was apparently due the fact that admission, death, and invaliding from malarial fevers were much reduced.

Year.	Strength.	Ratio per 1,000 of Strength.				
		Admissions into Hospital.	Constantly Sick.	Deaths.	Invaliding.	Total Loss.
1889–98	691,080	1,468	89	16·49	28	44
1898	67,741	1,437	90	20·05	38	58
1899	67,697	1,149	73	12·75	32	44

The chief causes of admission were venereal diseases and ague. Among the diseases with increased admission rates were influenza, small-pox, tubercle of the lungs, and pneumonia. On the other hand, the admission rates from cholera, remittent fever, ague, enteric fever, simple continued fever, bowel-complaints, hepatitic affections, and venereal diseases were lessened. Venereal diseases caused 27 per cent. of the total sickness, and ague 20 per cent.

The chief causes of death were enteric fever and hepatic abscess. Among the diseases with increased mortality were small-pox, pneumonia, and circulatory diseases. On the other hand, the mortality from malarial fevers, enteric fever, cholera, dysentery, and abscess of the liver was lessened. Enteric fever caused 40 per cent. of the total deaths, and hepatic abscess 10 per cent.

The chief causes of invaliding were, in order, syphilis and gonorrhœa, malarial fevers, debility, disordered action of the heart, and dysentery: syphilis and gonorrhœa, especially, and malarial fevers, being far ahead of the others.

Commands.—In the following table the ratios of the four commands are placed side by side for comparison. Bengal had the highest mortality from heatstroke, tubercle of the lungs, and dysentry; the Punjab the highest from enteric fever, remittent fever, pneumonia, and other respiratory diseases; and Madras the highest from hepatic abscess. All the commands were more healthy than in 1898.

Geographical Groups.—The following table shows that, judging by the constantly sick rate, Gangetic Plain, Central India, and Burma Inland were the most unhealthy groups for the decennium, and Hills and Western Coast the most healthy; that the decennial cholera mortality was highest in Gangetic Plain, and lowest in Western Coast; and that enteric fever mortality was highest in the Hills, and lowest in Burma Inland. In 1899 all the ratios, except the enteric mortality of Southern India and the Convalescent Depôts, were lower than those of the decennium :—

In the following table the vital statistics of the groups for 1899 will be found placed side by side to facilitate comparison. The most unhealthy group was Bengal-Orissa. Burma Coast had the highest admission rate from influenza, simple continued fever, tubercle of the lungs, and venereal diseases ; Bengal-Orissa the highest from ague, dysentery, and hepatic abscess ; Indus Valley the highest from small-pox, remittent fever, and pneumonia ; Central India the highest from enteric fever and diarrhœa ; Southern India the highest from hepatic congestion ; the Hills the highest from rheumatic fever ; and the Convalescent Depôts the highest from respiratory diseases other than pneumonia.

The percentage of dysentery and hepatic abscess to total admissions in 1899 was greatest in Bengal-Orissa ; of enteric fever, diarrhœa, and pneumonia in Hill Stations ; of simple continued fever and remittent fever in Indus Valley ; and of venereal diseases in Western Coast.

Stations.—The highest ratios amongst the large garrisons with a strength of over 1,000 were those of Peshawar (21·59), Lucknow, Umballa, and Bangalore (17·35). The first three were also in this black list in 1898, but their ratios in 1899 were greatly reduced, especially that of Peshawar. The Bangalore ratio, on the contrary, was higher than in 1898.

Regiments.—The statistics of individual regiments and of the different arms of the service show that the cavalry had the highest constantly sick and death rates, and an invaliding rate exceeded only by that of the artillery, which had the highest admission rate. The highest constantly sick rates in the various arms of the service were those of the 3rd Hussars, the 29th Battery, Southern Division, Royal Garrison Artillery, the 2nd Battalion, King's Own Yorkshire Light Infantry, and the 1st Battalion, Royal Warwickshire ; the highest death rates those of the 3rd Hussars, the 7th Battery, Eastern Division, Royal Garrison Artillery, the 72nd Battery, Royal Field Artillery, and the 1st Battalion, Royal Irish Rifles. This last was stationed at Dum-Dum and Calcutta after arrival in April from Natal, and its chief causes of death were dysentery, hepatic abcess, ague, and enteric fever. The principal loss of the 3rd Hussars at Lucknow was from enteric fever.

Principal Diseases : Influenza.—Sickness and mortality having been studied in their relation to India, to commands, to geographical groups, to stations, and to regiments, it will be convenient now to discuss the statistics of some of the chief diseases. At the end of 1898 and the beginning of 1899 influenza was falling. It began to rise in February, and reached its maximum for the year in May, though there was a rise again in October and November. The following table shows the increase of total in 1899. It also shows the monthly progress and the annual fluctuations of the disease since 1890, the first epidemic year :—

Period.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.	Per 1,000 of strength.
1890	—	3	473	1,451	248	69	13	2	3	—	—	1	2,263	33·4
1891	1	—	1	16	77	91	112	29	20	2	2	21	372	5·5
1892	113	53	354	241	57	4	32	8	—	—	—	—	862	12·7
1893	1	—	—	15	4	—	—	—	—	—	—	1	21	·3
1894	7	9	12	70	101	30	7	7	—	2	—	—	245	3·4
1895	14	7	52	156	66	35	17	1	5	13	23	165	554	7·8
1896	262	65	140	30	12	7	3	3	88	128	50	20	808	11·5
1897	12	10	31	9	11	30	8	8	—	54	87	12	272	4·0
1898	7	19	82	213	162	57	6	—	1	—	9	8	564	8·3
1899	6	10	145	136	167	79	42	11	1	12	59	6	674	10·0
Total	423	176	1,290	2,337	905	402	240	69	118	211	230	234	6,635	

The actual maximum of the individual years of the ten occurred in various different months, but over the ten-year period as a whole the greatest numbers of cases occurred in April and March, and the smallest numbers in August and September : 83 per cent. of the whole in the first six months of the year, and only 17 per cent. in the last six months. Geographical Groups I, II, V, VI, IX, XI, XII*a*, and XII*b* were attacked both in 1898 and in 1899 ; Group VII, which had escaped in the two years preceding, was affected in 1899 ; Groups IV and VIII, which had suffered in 1898, escaped in 1899 ; while Group X was spared in both years, as well as in the four years 1894-97. It is not

known why this last group, which contains the European garrison of Bombay, has been so long free from influenza. Twenty-eight stations were attacked in 1899, against twenty-five, over a dozen out of the twenty-eight having had no cases in 1898. Belgam, Ahmednagar, Chakrata, Ranikhet, and Rangoon had the greatest numbers of cases. At these stations the outbreaks were single and compact, except for a certain amount of tailing off in the case of Belgam. The returns deal, of course, only with those cases which were admitted into hospital. The only death returned as directly due to influenza occurred at Ahmednagar, where the disease, it is stated, was of a severe type. The Jhansi report mentions that the diagnosis between influenza and simple continued fever is variable; and the medical officer at Rangoon states that some of the cases returned as ague were probably influenza. In none of the reports is any mention made of the use of bacteriological methods as an aid to the diagnosis. In Europe it has been discovered that the bacillus may occur in the sputum or cling about the nose and pharynx for weeks and months. The microbe has also been found in the cerebro-spinal fluid and in endocarditic valve lesions.

Cholera.—General questions regarding the etiology, spread, and prevention of cholera, and the circumstances, so far as they are of importance, attending the occurrence of cases in 1899, will be found discussed under Chief Diseases (pages 91–101). The amount and proportion of cholera were much less than in the previous year, and the ratios were much below those of the decennium, as may be seen in the following table. There was only one case in the whole of the European army in India, and never before in the records of this office has so low a mortality appeared. The returns which come next are 12 cases in 1874, 16 in 1893, and 17 in 1898 :—

Period.	Admissions.		Deaths.	
	Number.	Per 1,000 of Strength.	Number.	Per 1,000 of Strength.
1889–98	1,053	1·5	764	1·11
1898	17	·3	14	·21
1899	1	·01	1	·01

The one case occurred in the 11th Battery, Royal Field Artillery, at Meean Meer, at a time when cholera was attacking the native troops as well as the non-military population.

Small-pox.—The admission rate from small-pox rose from 0·03 to 0·2, and the death-rate from 0·00 to 0·01. There were 14 cases with 1 death, against 2 cases without death. The ratios were still much below the decennial ratios of 1886–95. Peshawar and Nowshera, both in Group VII., had respectively 7 and 3 cases; but out of these ten, only one died. All the men affected bore marks of vaccination. The man who died was of intemperate habits, and was attacked with confluent small-pox. The disease was prevailing in the bazaars at the time, and the roads were very dry and the air dusty.

Ague, Remittent Fever, Simple Continued Fever, Malta Fever.—Ague gave rise to over 20 per cent. of the admissions from all causes. The admission ratio was low, and the death ratio lower than in the preceding year. The lowness of the ratio was probably connected with the dryness of the year.

Period.	Intermittent Fever.		Remittent Fever.		Simple Continued Fever.	
	Admissions per 1,000.	Deaths per 1,000.	Admissions per 1,000.	Deaths per 1,000.	Admissions per 1,000.	Deaths per 1,000.
1889–98	360	·22	14	·51	42	·02
1898	394	·30	33	·37	43	·06
1899	235	·28	10	·16	32	·01

The following table shows that the group-incidence of ague was somewhat abnormal in 1899, as it had been in 1898, this being apparently connected with the fact that the monsoon rainfall of the east was abundant, that of the west and south deficient :—

Period.	Ratio per 1,000 of Strength.												
	I.	II.	IV.	V.	VI.	VII.	VIII.	IX.	X.	XI.	XII*a*.	XII*b*.

South-Eastern Rajputana, Central India, and Gujarat.	Deccan.	Western Coast.	Southern India.	Hill Stations.	Hill Convalescent Depôts and Sanitaria.	India.
1889–98...	178·9	387·1	404·9	226·4	458·3	731·8	482·9	251·1	157·4	139·9	252·4	285.7	359·8
1898 ...	56·3	171·4	603·5	314·8	550·3	766·3	499·1	320·6	115·0	278·1	224·8	43·0	394·0
1899 ...	187·4	383·1	658·1	195·7	267·5	276·9	230·9	209·5	148·4	274·9	103·6	216·7	235·2

In the Bengal-Orissa group the most malarious stations were Barrackpore and Dum-Dum. The medical officer in charge at the former says that it is situated on low-lying alluvial soil with insufficient drainage, surrounded by rice cultivation and stagnant tanks ; but he acknowledges that the drainage has been greatly improved by the measures completed in 1898, and to that attributes the reduction of malaria in 1899. At Dum-Dum the soil is said to be water-logged. In some station reports the inter-fluctuations in the diagnosis of ague, simple continued fever, and influenza are noticed. The most malarious months of 1899 were August, October, and September, and the least malarious, as usual, February. The rise of malaria and its acme were both earlier in the year than usual. This appears to have been connected with the distribution of the rainfall.

Remittent fever was much reduced in 1899. The disease was most prevalent at Peshawar, Attock, Delhi, and Shwebo. At Shwebo the disease, often of a severe type, was in all cases contracted in the very malarious forests to the north-east of the station, where, towards the end of the rains, the natives had been dying in numbers of the same disease. Remittent fever in 1899 was most prevalent in August and May, and least prevalent in February. Eleven men died, and ten of the bodies were examined. In five no very definite lesions were discovered ; in one there was pneumonia, said to have supervened ; in one there was an abscess of the liver ; in one there was an abscess between the spleen and the liver ; in one there was yellow lymph on the brain, especially under the medulla and pons ; and in one the lymph glands, especially the mesenteric, as well as the spleen, were enlarged and soft, and Peyer's patches were stripped of their epithelium. At Barrackpore cases suspected of being enteric fever, but not re-acting to Widal's test, were returned as remittent fever, even though they did not respond to the exhibition of quinine.

Simple continued fever was also much reduced. It was most prevalent at Nowshera, Aden, Madras, Port Blair, Peshawar, and Thyetmyo. The causes mentioned at these and other stations are sun, heat, over-exertion, want of acclimatization, especially when combined ; chill, exposure, constipation, errors in diet and drink. Some of the cases were suspected to be enteric fever, or malarial fever, or influenza, or Malta fever, or some yet-undifferentiated fever ; and the employment of the serum test is said at Rawalpindi to have led to the smallness of the number of cases returned as simple continued fever. One man, whose case was returned as simple continued fever, had been 84 days under treatment. He had a stricture of the urethra ; and the examination of his dead body revealed the presence of a single abscess of the liver, and "dysenteric ulcers" of the large intestine and of the lower third of the ileum. In 1899 most simple continued fever was registered in July, and least in January. The admissions from simple continued fever fell from 1886 to 1891, rose in 1892, fell up to 1894, rose to 1897, fell slightly in 1898, and fell considerably in 1899. The height of all the fever ratios in 1897 and 1898 and their fall in 1899 were apparently connected with the progress and cessation of field service on the

frontier. From 1886 to 1894, while simple continued fever was on the whole falling, ague and enteric fever were on the whole rising. If the causes of simple continued fever be as given above, it seems easy to understand why in the European army men are most attacked and women least, and why natives suffer less than Europeans, though there is perhaps also in the native military hospitals a tendency to call most short mild fevers ague.

1890–99.

* No Troops.

It is curious to note that both European and native troops have high ratios in the Western Coast and Southern India groups.

Only one case of Malta fever was returned from Kalabagh; but the medical officer does not mention the case in his "Transactions." Just at present a number of cases of Malta fever are being discovered in India both among Europeans and natives; but the experience of the past should warn those in authority, while encouraging the research, to exercise a certain amount of reserve in the acceptance of at least the earlier results. After all, serum diagnosis is still in its infancy, or is just emerging therefrom.

Enteric Fever.

The Goulstonian lectures for 1900 by Horton-Smith form the most valuable recent contribution to the literature of enteric fever on its scientific side. Some of the more general conclusions of Horton-Smith are as follows:—

The typhoid bacillus can always be found in the stools in the early periods of the disease. It can also be demonstrated always in the Peyer's patches and the mesenteric glands. It does not, however, remain limited to these situations, but very soon, and in all cases, passes into the blood (from which it can often be isolated), by means of which it is distributed to the most diverse organs. Thus it can be always found in the spleen and in the liver. It gives rise in the skin to the typical eruption. It is in most cases present in the marrow of the bones and in the bile. It is frequently present in the urine, and is not uncommonly found in the kidneys. Occasionally, also, it may be detected in the lungs, and sometimes in other organs . . . Any conception of the disease which regards it merely as affecting the alimentary canal only can no longer be maintained. On the contrary, so far from considering it as an intestinal disease pure and simple, we should rather look upon it as a *modified form of septicæmia*. It is septicæmia in that always and in all cases the bacilli pass into the blood and then into the various organs, and in that the symptoms, excepting as far as they are intestinal, are referable to the poisons there produced. It is a modified form, however, in that in nearly all

cases there is a definite local and primary disease, whence the secondary dissemination of the micro-organism takes place. Looked at in this way, we have a ready explanation of the fact that the severity of the disease bears no relation to the number and character of the intestinal lesions. For just as a fatal septicæmia may originate in a scratch, so one or two small typhoid ulcers may be quite sufficient to allow the entry of the micro-organism and the development of the disease.

Urine.— The subject of the urine in its relations to the enteric bacillus was fully treated of in last report. It may, however, be added that Horton-Smith considers the bacilluria to be due, not to continuous renal excretion of bacilli, but to the multiplication in the bladder of a stray bacillus or two from the kidney.

Fæces.—Remy claims by the use of a new medium to be able to isolate the enteric bacillus, and to differentiate it from the colon bacillus. In the examination of 23 cases he found the bacillus once on the 3rd, 4th, 6th, 13th, 14th, 21st, 22nd, and 30th days; twice on the 42nd and 45th days; three times on the 10th and 16th days; and four times on the 5th and 9th days. His experience is that the bacilli are few at first, more numerous in the second week, fewer again in the third and fourth weeks, and disappear gradually or, at least, cease to be detectable by present methods. All the bacilli from the stools were of the same type, re-acting negatively with regard to the production of indol and fermentation, and positively towards enteric serum. He regards the finding of the bacillus in the stools as the only certain sign of enteric fever, and the only sign which in a doubtful case is sufficient of itself to establish a positive diagnosis.

The Roseola.—The efficiency of the method of Neufeld, noticed in last report, for obtaining the bacillus not only from the roseola, but also from the general circulation, has been confirmed by subsequent observers. But Eug. Fraenkel has gone a step further with regard to the roseola. He exercised roseola spots in five cases, and kept them, with proper precautions, at 37° C. for 18 hours, in order to cause the probably sparce bacilli to multiply. In stained sections he was then able to find little heaps of enteric bacilli lying in the papillary portion of the cutis; and thereby to demonstrate that the roseola is not merely a hyperæmia, but a local lesion caused by the bacillus.

Soil. Dust.—In a leading article on the endemic fever of English towns, with special reference to the report of the Medical Officer of Health of Chichester, the *Lancet* makes some remarks interesting to sanitarians in India, of which a couple of sentences may be quoted :—

> Specific pollution of drinking water, milk, shell-fish, ice-cream, and the like may, indeed, now and then have caused an increase of the customary amount of enteric fever; perhaps a particular period of sustained fever prevalence has seemed to have been started by an outbreak which was traceable to infected food or drink; but the appearance of inenteric fever year after year in excessive amount has quite certainly not been occasioned by recurring exposure to infection by such agencies . . . To admit that enteric fever may be locally spread by the way of the diverse and obvious opportunities of fection afforded by recently and specifically polluted surface soil, brings us, it is to be feared, little nearer to obtaining the causation of endemic enteric fever . . . A satisfactory explanation seems to require the further proposition that in certain cases the typhoid bacillus must be capable of maintaining for weeks and months an active existence in soil.

Barr, too, remarks that while fresh water supplies have lessened or almost abolished widely-spread epidemics, yet as an endemic in many large centres of population enteric fever is as prevalent and of as severe a type as it was a quarter of a century ago.

In connection with the above it may be noted that Horton-Smith, in the lectures referred to, after mentioning that there is no proof that the enteric bacillus can multiply outside the body, and that many outbreaks may be explained by the prolonged infectiousness (see the report for 1898, paragraph under "Urine") of persons apparently restored to health after an attack of the disease, goes on to say that if it be remembered that the bacillus has great power of resisting the effect of desiccation, remaining alive, it may be, for over a year in the dried condition, it becomes easy to understand how bacilli eliminated from the body may later pass into the atmosphere in the form of dust, and cause disease at long periods after every fresh source of infection has been really removed; that these facts should, in many cases at least, render unnecessary a belief in the actual growth of the bacillus outside the human body; but that the question is one which the future alone can finally settle.

Water. Filters. Chemical Purifiers.—A case is reported from Europe in which a battalion, after taking part in certain manœuvres, developed 30 cases of enteric fever, and the enteric bacillus was found in the well from which water had been supplied to this battalion only. At Cuxhaven Dunbar could not find the enteric bacillus in the water of a well round which cases of enteric fever had occurred, but found it in a well surrounded by a population that appeared free from the disease. But a week after, 20 cases occurred

in this second population. It has been estimated that the enteric bacillus disappears when in competition with the saprophytic organisms of water in about two weeks ; but it is difficult to find it in water at any time. Hankin's method, which was fully described in last report, was tried by Hilbert in Germany, who reported that it was good so long as the colon bacillus was not present at the same time. To this criticism Hankin has replied, pointing out that Hilbert in his laboratory experiments omitted to acclimatize his enteric microbes to life in water ; that in his examination of suspected waters he did not test enough samples of each ; that he did not wait till he had become a practised worker with the method before reporting on it ; and, finally, that Adami in Canada has reported favourably on the method from practical experience. ' Hilbert having also asserted that "only a fraction" of the cultures submitted by Mr. Hankin to Professor Pfeiffer were acknowledged by the latter to be true enteric, Mr. Hankin referred to Professor Pfeiffer, and obtained a reply that the expression referred only to some cultures he had seen in Bombay, and that "nearly all" those sent to Berlin were true enteric. So great is the difficulty of finding the enteric bacillus in water—or, at least, so rarely is it found—that Professor Carl Fraenkel advises those who send specimens to him for examination not to wait for the result, but to go on with the precautions they would have taken if the bacillus had never been discovered. Endeavours are therefore made to find other bacteriological criteria of probable danger in water ; but here the difficulty of forming a judgment is greatly increased by the occasional occurrence of eberthiform (enteric-like) and colriform bacilli, *i.e.*, of microbes which form a graduated series between the enteric bacillus on the one hand and the colon bacillus on the other, and partake in degrees of the characters of both ; so that it is a laborious task to identify not only the enteric but even the colon bacillus. In fact, some practical bacteriologists attempt to avoid the difficulty by condeming all waters in which such intermediate forms, or the colon bacillus itself, occur, at least in any considerable number, constantly or in spates ; believing that they are not only signs of danger, but actually themselves constitute the danger. But, just as an outbreak of enteric fever sometimes occurs in a community whose water-supply appears bacteriologically pure, so occasionally a water reported dangerous by the bacteriologists fails to produce an outbreak. One difficulty is that while some of these intermediate forms appear to be water-bacteria, no one has succeeded in reconciling either the enteric or the colon bacillus to a permanent aquatic life. Vaillard having stated that he had seen the enteric bacillus present for long periods in very pure water, Löffler replied that if so it must have been continuously introduced into the water ; for in his experience the bacillus only lived for 24–48 hours in very pure water, and for not more than 15 days in natural water, though it might live longer and even multiply in contaminated water. Again, Lunt did not succeed in acclimatizing the normal intestinal colibacillus to water. However, it is conceivable that the acclimatization-process may nevertheless be worked out in the better furnished and more slowly working laboratory of nature. Levy and Bruns state that if the suspected water be "enriched" by the addition of peptone and salt and by incubation at 37° C. for 48 hours, and then be injected in respectively appropriate quantities into guinea-pigs, rabbits and mice, the result to the animals will show whether any colon or proteus bacilli present were virulent, and therefore signs of impurity, or non-virulent, and therefore signs of purity. They state that animals never die from the injection of *pure* water. The results of Weissenfels, just published, do not, however, support those of Levy and Bruns. Pakes affirms that a water which shows a great variation in the number of bacteria present from time to time must be considered just as unsafe as one which shows variations in chemical composition ; that the presence of the colon bacillus in the water from a deep well in any quantity is sufficient to condemn it ; that drinking water not from a deep well, if it contains the colon bacillus in 20 c.c. or less, should be condemned ; if it contains the coli bacillus in any quantity between 20 and 50 c.c., should be looked upon as suspicious ; if it contains the same organism in from 50 to 100 c.c., should be regarded as slightly suspicious ; if the bacillus is found only in quantities greater than 100 c.c., may be looked upon as probably safe ; if no colon bacilli can be obtained from two litres, may be considered absolutely safe. The presence of the *Bacillus enteritidis sporogenes* too has been proposed as a test, but the researches of Hewlett show that the exact value of the test cannot yet be appreciated. The use of a chemical test for cystine has been introduced by M. Causse, who considers the occurrence of cystine in a water to indicate the presence of the germs of typhoid fever. The purification of water is attempted by the aid of heat, by the addition of chemicals, or by the use of filters. Vincent at the Paris International Congress stated that the Pasteur and Berkefeld filters were about equal ; but that even when sterilized they do not give a water rigorously and constantly aspetic, and that every few days they must be sterilized

anew. With regard to the Berkefeld filter, Lunt reports that although the filtrate obtained was not absolutely sterile after the first day, yet neither the colon bacillus nor the enteric bacillus could be detected in the filtrate over periods of 39 and 26 days respectively, although they were easily found in the water outside the filter for 39 and 26 days respectively. In India, as elsewhere, a good deal is now known of the practical inconveniences and dangers of the use of filters, and of the extreme care which they require. Weyl in Germany and A. Calmette in France have strongly supported the claims of ozone to be the best and most successful purifier of water, even on the large scale ; and Plagge and Schumburg have published a useful short paper on all the best or most frequently used chemical methods, including the well-known permanganate and bromine processes. From France come favourable reports of potassium permanganate, so much used also in India.

How little after all is really known about the bacteriology of water, and about the necessity and the best means for the sterilization of water, is shown by the report of a discussion on these subjects by eminent bacteriologists of more than one nation at Paris on the 16th of August, 1900.

Milk, Eggs.—Hesse, agreeing with the previous results of Theobald Smith, points out that if while milk is kept at 60° C. for 15 to 20 minutes, a pellicle is not allowed to form, the bacilli of enteric fever, cholera, diphtheria, plague and tubercle are all destroyed ; while Macfadyen and Hewlett found that in their apparatus 30 seconds at 70° C. killed the enteric, tubercle, and diphtheria bacilli, and the staphylococcus. Bucco asserts that the enteric bacillus is able to enter into an unbroken egg in twelve hours, and to keep its vitality therein for four or five days.

Flies.—Some results of Hankin's with regard to flies are quoted below. Vaughan has published 53 conclusions derived from a study of the enteric fever of the American army camps, and one of them is that flies undoubtedly served as carriers of the infection. Chiene also speaks of dust and flies as disseminators of the disease in South Africa.

Colibacillus fever, Tropical fevers.—Both Burney Yeo and Rho mention the fact or the possibility of the occurrence of cases indistinguishable clinically from enteric fever, but caused by the colon bacillus. Rho considers that in hot countries medical men attribute too much to malaria and too little to enteric fever ; and believes that nearly all "climatic" fevers and common continued fevers are enteric fever. It has, too, been pointed out by Osler and others that even in a malarious locality a continued fever irresponsive to quinine is in all probability enteric fever, and should be considered such until proof to the contrary is obtained. Osler and Rho regard the co-existence of enteric fever and malarial fever in the same patient as excessively rare.

Some cases were quoted in last report. Rho mentions 1 more, and Kerr 5, in which both the plasmodium and the bacillus were present. The case reported by Yarr is incomplete, the proof given of the presence of enteric fever being entirely clinical. McNaught has lately published two cases.

Enteric fever and dysentery.—Washbourn, Richards and Washbourn, Sir William Stokes, and Watkins Pitchford have all reported from South Africa cases of the co-existence of, or very close connexion in time between, enteric fever and dysentery. Similar cases in India are noticed below, and have been noticed in previous reports. The dysenteric bacillus isolated by Flexner in the Philippines belongs to the enteric group.

Second attacks.—Nearly every year this report cites one, or it may be two, cases in which second attacks of enteric fever have occurred in one patient. Remlinger in the case of 628 French soldiers attacked by enteric fever obtained in 16 a certain and in 5 a doubtful history of previous attack ; four cases came under his own observation ; and he is able to cite 31 more observed by others.

Incubation.—The question of the length of incubation of enteric fever constantly comes up in India in connexion with the decision as to where cases originated—locally, or on the march, or in another station. Vaughan puts it as from something under 8 days to any time within 8 weeks ; another writer as from 10 days to 3 weeks. Engel went over all the literature available to him, but could only find 88 cases that could be safely used, and even of these a few showing periods of 1, 2, 33, 42, 45 days were ultimately rejected as doubtful. But incubation periods of from 4 to 32 days were regarded as fully established, the most frequent being 14 days, then 18, then 21, then 8.

Cause of relapses. Cause of falling ill.—Horton-Smith, in the lectures already referred to, has some interesting remarks on the causation of relapses in enteric fever. Put shortly, the idea is that at a time when all the enteric bacilli have not yet been destroyed in the patient, an absorption of toxines (*e.g.*, those of the colon bacillus, Gaertner's bacillus, or of the proteus) takes place from the intestinal canal (auto-intoxication), giving the enteric bacillus a fillip, and enabling it to acquire fresh virulence and to re-invade the patient's organism. But the same explanation might be applied to the original succumbing of the patient to the enteric infection ; for it may be that, in some cases at least, disease only follows when, as the result of some trifling derangement of the bowel, the soil has already been prepared by the absorption of toxic products, or, in other words, by auto-intoxication. Ord, however, offers quite a different explanation of relapses—self-re-infection of the patient by putting his soiled fingers into his mouth.

Opinions of medical officers.—As usual, a factor most commonly insisted upon by medical officers was recent arrival in India of regiments, or of drafts, coupled with youthfulness of the men. In a few cases it is stated that particular regiments or barracks were especially attacked. Proximity to sewage irrigation, to filth pits, to an incinerator, to a latrine, to disused latrine-ground, to an enteric ward, and conveyance by flies and dust to the mouths of men, to food, and to cook-house water, are the chief points mentioned in this connexion. In other stations, too, dust and flies are mentioned as probable agents of infection, and the prevalence of enteric fever is connected with the dryness of the year and the frequency of dust storms. The medical officer at Peshawar believes that systematic road-watering would be a powerful preventive ; while the medical officer of Agra points out that in June enteric fever was rare, though dust-storms were frequent, no cases occurring between May and August. At Quetta one man was believed, and believed himself, to have been infected by the dust inhaled in pulling down an old latrine ; while at Chakrata the site of a removed latrine was used for playing quoits by the men of a regiment affected. The water, aërated water, milk, sweetmeats, food, &c., obtained in bazaars, brothels, and villages were, as usual, strongly suspected by nearly all medical officers. At Deesa one man admitted for soft chancre developed enteric fever in hospital, and he was found to have bazaar sweetmeats concealed in his bed. While the barracks at Agra were furnished with purified well-water, infected pipe-water was supplied to the bazaar, and the latter had to be placed out of bounds. The same measure was adopted at Poona on account of the plague, and at Umballa and Peshawar, and it is said to have reduced the amount of the disease. Some patients acknowledged the drinking of water from unauthorised sources in the station ; some of water direct from the tap, instead of the specially purified water provided for them ; while others out shooting in the jungle, or walking in fields or villages, or at exercise, or in camps of exercise, or rambling about khuds in the hills, or travelling by railway, drank water or milk evidently impure, or not known to be pure. For the 47th Battery, Royal Field Artillery, at Ferozepore, a polluted well-water, containing the colon, but not the enteric bacillus, was by mistake taken into use on the 11th May. Its use was discontinued on the 14th May. The dates of admission of enteric fever cases in this battery during the year were—April 21 ; May 5, 7, 12, 16, 19, 22, 23, 24, 26 ; June 16 ; and December 30. The cases which occurred early in January at Bangalore were apparently associated with the presence of the enteric bacillus in water used in the horse-lines. At Agra, while every care was being taken of the drinking water, it was found that aërated waters were being manufactured from unboiled water of the frequently specifically impure pipe supply. Not only was the bazaar at Shwebo supplied with a foul water from the King's tank, but during the rains that tank overflowed into the reservoir set apart for the storage of the drinking water of the troops, and the men were suspected of drinking the mixture direct from the tap. The impure water of the lake at Meiktila was considered likely, directly or indirectly, to be the source of the infection. One patient at Dagshai had drunk morning and evening for a month milk procured from a native in the floor of whose house a cesspit was found. The combined result of seven stations was that 50 cases occurred among total abstainers and 90 among non-abstainers, or 36 and 64 per cent. respectively. But, as their average annual strengths cannot be obtained, no conclusion can be drawn as to the relative liability of those two classes. Some medical officers lament that the purificatory measures applied to the water of late years have not produced the hoped for result ; while others state that the history of enteric fever in their stations shows that the water supply is not there the source of the disease. That the cavalry and artillery at Bangalore suffered more than the infantry was believed to be due to the fact that their barracks were near an open sewer, and a filth depôt, and a lucerne

crop irrigated by sewage ; and perhaps also to the vicinity of the horse-lines, with their dust, and flies, and contaminated water. The effluvia of the Ahmednagar filth-pits were believed by the medical officer of that station to have had something to do with the causation of the disease. In a good many cases patients dated their illness from a chill after being heated, from over-exertion or exposure, from fatigue, from exposure to the sun. In other cases the attack was preceded by the eating of water-cress, of tomatoes, of tinned salmon, which caused diarrhœa ; while the medical officer of Colaba mentions that men had been seen eating small shell-fish picked up on the polluted foreshore. At Quetta recent arrival there was considered to be a factor in the local causation of cases. Medical officers frequently noted, especially in the case of hill stations, that the disease must have been contracted before arrival, either from impurities encountered on the march, or from a cause existing in the previous station ; so that the station where the disease was treated was not always the station in which it was contracted. Several cases of men new to India were noted by the medical officers of Meerut, Dagshai, Ferozepore, Khyragully, and Kalabagh, as having apparently contracted the infection on the way up country from Bombay ; and in two Calcutta cases the infection is said to have been probably contracted in South Africa. Some officers, as usual, state their belief that enteric fever and venereal disease are contracted in the same haunts. The contamination of latrines by ambulant cases, and the subsequent dissemination of the disease by flies and dust, are among the possible dangers noted ; and in one case the attack was ushered in by a severe, possibly pythogenic sore throat, in another by diarrhœa lasting 14 days before the man reported sick. At Fatehgarh, Cawnpore, Umballa, Meean Meer, Murree, Madras, Rangoon, Mandalay, Poona, Agra, and Ahmednagar, also, the water supply is said to be liable to contamination ; and the possibility of danger in the carrying of the water, either from the mode of carriage or from the distance to be traversed, is noted at Allahabad, Dinapore, Cawnpore, Ranikhet, Jutogh, Kasauli, Cambellpur, Ghora Dhaka, Bellary, and Ramandrug. That dangerous arrangement, a double water-supply, still obtains at Calcutta, Agra, Madras, Wellington, Secunderabad, Thayetmyo, Shwebo, Satara, and Nasirabad. The fact that the simultaneous supply of two waters of different degrees of purity may occasionally be the only permanent or temporary possibility, does not make it any less undesirable. With regard to only six stations, it is stated that the water needed, and received, no purification before issue for consumption. Usually the water was boiled, sometimes in Larymore boilers, and was treated with potassium permanganate, alum also being occasionally used. The use of Pasteur filters is also mentioned, especially with reference to the aërated water factories. At Agra, Chakrata, and Wellington the process of sterilization is said to have been improperly carried out, and was therefore useless, or worse than useless. Though it is practised in many stations, only a few reports mention the incineration of excreta. It appears that the perfect incinerator has not yet been found, and experiments are being continued. As usual, some medical officers recommend the dismissal of the native cooks, and the transfer of the cooking to the hands of specially trained soldiers. The enteric bacillus was detected in samples of water from Agra, Wellington, Bangalore, and Neemuch, to which, according to Mr. Hankin's annual report, should be added Chakrata ; an enteric-like bacillus in water from Umballa ; the *bacillus coli* in water from Lucknow and Ferozepore. Some other medical officers state that the result of bacteriological examination was negative, or that no examination was made, while some do not notice the point at all. With regard to Wellington, the medical officer points out that while 300 persons drank of the infected water only two got the disease. In several stations the Grünbaum-Widal reaction was used in the diagnosis of cases, and at Rawalpindi the bacillus was frequently cultivated from the spleen. The medical officer at Fort Lahore notes that no women, no children, no members of the permanent staff were attacked. That the women and children at Sialkot were completely exempt seems to the medical officer to point to the bazaar-haunting habits of the men as a factor in causation if it were not for the difficulty that the officers and ladies are not exempt. At Wellington there were no cases among the women and children, though one of the men attacked was a married man. Both at Barrackpore and at Agra it was noticed that civilians, using the same water, suffered much less in proportion than soldiers. In the extracts given below it is claimed that the measures adopted at Cherat and Bangalore were successful in reducing the amount of enteric fever, and those put in force at Quetta were also accompanied by a great diminution of the number of cases. Cases in which placing the bazaars out of bounds is said to have been efficacious have been given above. Calcutta, Roorkee, Poonamallee, Rangoon, Port Blair, and Mandalay are reported usually to enjoy comparative immunity. The explanation given for Calcutta is the good water-supply ; for Roorkee the presence of grass and the consequent absence of water-defiling

dust ; and for Mandalay good luck and the unattractive taste and colour of the impure water. The decrease at Jullundur is ascribed to the selection of wells, the boiling and permanganating of the water, and sending away of young susceptible men to the hills ; at Peshawar to the bazaar being out of bounds, and to the men not having been anxious to visit it on account of one of their number having been murdered therein by a fanatic ; at Meiktila, possibly to the fact that the drinking water has been boiled since April 1896. The reduction at Mhow the medical officer confesses himself unable to explain. The personal element among men equally exposed to infection was emphasised by the medical officer at Wellington, while at Agra the harvest and the rise and the fall of the river were found to be contemporary with the maxima of the disease. The French idea of the possibility of the transformation of the colon bacillus into the enteric bacillus was considered at Mhow. Some medical officers considered that enteric fever after a previous prophylactic inoculation was comparatively mild. Out of the 1,392 cases of enteric fever which occurred throughout the army of India in 1899, 24 are noticed as having declared themselves among patients in hospital or among attendants. Out of these 11 were in hospital for early venereal disease, except that in one the enteric fever was observed before the venereal disease (gonorrhœa), and eight for other diseases, and five were attendants on enteric fever cases. The number of attendants attacked was low as compared with the number in each of the two years preceding. Cases of second attack were reported from Ranikhet, Jhansi, Chakrata, Madras, and Bangalore. The first attack of the Ranikhet man had been at Quetta nine months before. Fhe Jhansi medical officer records that there was no *post-mortem* evidence of the former attack, which was said to have occurred at Subathu in 1898. The man affected at Chakrata was said to have had a first attack in 1897, and had also been inoculated in January, 1899. The first attack in the Madras case occurred six years ago, while the Bangalore man had had his first attack, with relapse, in August, 1898. In two of the fatal cases at Ranikhet the *post mortem* appearances were abnormal. In the first the only intestinal lesion was a perforating ulcer, $\frac{1}{4}$ of an inch in diameter, in a Peyer's patch, about $2\frac{1}{2}$ feet from the lower end of the ileum ; in the other the only intestinal lesion was a non-perforating ulcer, the size of a split pea, in a Peyer's patch about 6 inches above the lower end of the ileum. Cases in which enteric fever and dysentery were closely connected in time were observed at Agra, Chakrata, and Meiktila. At Agra and Meiktila the dysentery immediately preceded the enteric fever ; at Chakrata the dysentery supervened on recovery from enteric fever. A case each of enteric fever at Jubbulpore, Dalhousie, Bangalore, Rawalpindi and Poona was complicated with abscess of the liver. The Bangalore case was not examined *post mortem* : in three of the other cases the abscesses were multiple. Again, in six cases returned as abscess of the liver from Bareilly, Ranikhet, Umballa, Poona, Ahmednagar and Kirkee, the origin of the abscesses was with more or less certainty suspected to have been the intestinal ulceration of enteric fever. In only two of these cases was there actual ulceration at the time of death ; in two there were scars and signs of the preceding enteric fever, while in two there was nothing to go upon but a history of recent enteric fever.

Medical officers also reported on the outbreaks of 1899, of their supposed causation, especially of their connection with polluted drinking water, of the measures considered to have been effectual in preventing or checking the disease, and of any other points of interest brought forward. From the following table it will be seen that there was at last a reduction in the amount of enteric fever in India :—

Commands.	Year.	Enteric Fever.		
		Admissions.	Ratio per 1,000 of strength.	Difference.
Bengal	1898	824	41·1	− 18·3
	1899	485	22·8	
Punjab	1898	895	48·7	− 23·8
	1899	451	24·9	
Madras	1898	143	11·6	+ ·5
	1899	156	12·1	
Bombay	1898	513	35·1	− 15·7
	1899	300	19·4	
India	1898	2,498	36·9	− 16·3
	1899	1,392	20·6	

No general explanation can at present be offered as to the rise in Madras and the fall in the other commands, especially as Madras received 2,422 fewer, and Bombay 98 more, fresh arrivals than in the preceding year. In the Bengal command 24 out of 33 stations shared in the decrease of ratio, chief among them being Shahjahanpur, Jubbulpore, Muttra, Agra and Lucknow ; in the Punjab command 19 or 20 out of 30, especially Fort Lahore, Cherat and Nowshera, Kalabagh on the other hand showing a great increase. The disease decreased in only seven out of 20 Madras stations, and in six out of 22 Bombay stations, but the decrease in the Bombay station at Quetta was very great :—

Years.*	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
1898	2	...	...	...	2	5	37	56	48	60	21	1
1899	.	...	3	...	...	..	1	7	6	7	2	...

the total being reduced from 232 to 26. This great reduction at Quetta may fairly be considered, at least provisionally,* as due to the detailed and painstaking measures adopted in consequence of the outbreak in 1898, though it will be noticed that the season of maximum prevalence was the same in both years. The number of fresh men arriving in drafts was much the same as in the preceding year.

Enteric fever in 1899.—There was a great decrease of both morbidity and mortality from enteric fever in 1899. The admission ratio fell from 36·9 to 20·6 and the death ratio from 10·17 to 5·14, a difference of 16·3 and 5·03, and a percentage reduction of 44·17 and 49·46 respectively. The reason for this is to be found, perhaps, not so much in the climatic conditions of the year, as in the facts that the influx of drafts from England was much smaller than usual, and that there was no field service. There were 1,392 admissions and 348 deaths, against 2,498 and 689 in 1898. The average number of men constantly sick from enteric fever, excluding those at Lundi Kotal, was 213, and the average duration of a case, with the same exclusion, was 56 days. The total loss of service due to the disease was about 77,818 days, the men at Lundi Kotal being excluded from the calculation, because the requisite data were not furnished for them. At the stations of Barrackpore, Bareilly, Chaubuttia, Solon, Rawalpindi, Peshawar, Colaba and Quetta, at least, the Grünbaum-Widal test was employed as a means of diagnosis. The results of the preventive inoculations with dead bacilli after the manner of Wright is commented on under General Remarks (page 150).

Fever mortality.—The following table shows an increase in total fever and in enteric fever, and a decrease in "other fevers" progressive through three decennia. It will be observed that the increase in enteric fever began suddenly in 1878, the year in which the short service system probably began to affect India, and the year which saw the commencement of the Afghan war :—

Fevers.	1870.	1871.	1872.	1873.	1874.	1875.	1876.	1877.	1878.	1879.	1870–79.
Enteric Fever ...	1·59	1·62	1·87	1·34	1·70	1·44	1·82	1·60	3·64	3·59	2·03
Other Fevers† ...	2·56	1·74	1·38	1·11	·86	1·04	·59	·56	1·43	2·96	1·42

* Intermittent, remittent, and simple continued fevers.

During the three years of the Afghan war, 1878–80, the ratio was high. Afterwards it was lower for four years, but it never again fell to the low level of the previous decennium. It rose in 1885–86 with the onset of the Burmese war, and again very steeply and suddenly in 1889 for some unknown reason. After this it was lower for a time, but never returned to the level of the 1880–89 decennium. There was another sudden increase in 1897–98 with the outbreak of the Afridi war. With each of these sudden rises of enteric fever there was also a rise of "other fevers," which might be held to point to the hardships of war if it were not for the case of 1889. It looks as if the persistent increase of the disease were due to the continuous supply of susceptible subjects, and perhaps to the greater abundance of germs derived from cases; and as if a sudden aggravation by field service or some other cause were never quite recovered from, the disease indeed falling, but never again to its former level. This would appear to mean an increase in the amount of virus ready for work throughout the land; and for such a state of things the only remedies would be the artificial immunization of the soldier and the total destruction of *all* the excretions of enteric patients. At the same time it must not be forgotten that the progressive increase of enteric fever was partly due to the gradual recognition of the frequency of the disease in India.

Enteric Fever in the geographical groups.—The following table shows enteric fever in the geographical groups in the decennium 1889–98, and in the last two years :—

Admissions per 1,000.

Period.	Burma Coast and Bay Islands.	Burma Inland.	Bengal and Orissa.	Gangetic Plain and Chutia Nagpur.	Upper Sub-Himalaya.	North-Western Frontier, Indus Valley, and North-Western Rajputana.	South-Eastern Rajputana, Central India, and Gujarat.	Deccan.	Western Coast.	Southern India.	Hill Stations.	Hill Convalescent Depôts and Sanitaria.
	I.	II.	IV.	V.	VI.	VII.	VIII.	IX.	X.	XI.	XII*a*.	XII*b*.
1889–98 ...	9·3	5·0	11·6	31·2	29·4	19·6	32·3	20·2	7·6	15·4	33·9	14·8
1898	7·3	4·5	19·3	44·1	36·6	29·6	47·1	25·7	2·6	19·3	59·7	20·3
1899	5·8	4·1	8·1	22·4	24·6	14·9	31·9	20·0	6·8	20·4	25·5	22·0

It shows that Groups V, VI, VIII, and XII*a*, are apt to have high ratios of admission from enteric fever; and Groups II and X, and, to a less extent, I and IV, low ratios. It also shows that in most of the groups enteric fever morbidity was unusually low.

Enteric fever in stations.—The following shows the distribution of enteric fever in those garrisons which had an average strength of over 1,000 in 1899, with the decennial ratios for reference :—

Stations.	1899.		Decennium, 1889–98.	
	Admission-rate.	Death-rate.	Admission-rate.	Death-rate.
Chakrata	64·4	8·70	36·8	7·99
Rawalpindi	38·4	7·37	28·6	7·88
Bangalore	36·6	7·43	20·3	3·90
Lucknow	32·6	8·76	40·2	9·50
Umballa	32·0	8·97	31·1	8·11

Stations.	1899.		Decennium, 1889–98.	
	Admission-rate.	Death-rate.	Admission-rate.	Death-rate.
Mhow	29·3	8·37	35·1	8·52
Ranikhet	29·1	4·85	36·5	6·13
Agra	27·2	8·23	48·6	13·60
Allahabad (including Fort Allahabad.)	26·4	8·79	34·6	9·36
Peshawar	25·3	9·87	30·1	12·89
Meerut	24·6	9·31	35·6	10·23
Secunderabad ...	16·8	3·14	25·2	6·03
Bareilly	15·5	3·11	40·5	10·12
Sialkot	14·4	3·85	33·0	7·27
Wellington	13·9	2·99	8·8	2·75
Kamptee	11·4	4·73	12·2	3·60
Quetta	10·8	2·08	30·7	6·99
Poona	9·0	2·12	18·1	5·02
Colaba (Bombay) ...	7·9	1·58	4·2	1·71
Belgam	7·1	3·56	2·9	·66
Aden	6·4	1·83	4·9	2·45
Rangoon	5·6	1·88	9·6	3·09
Fort William	3·6	·91	5·4	1·73
Fort Dufferin (Mandalay.)	1·0	—	6.1	2·16

The high position occupied by the decennial admission ratios of Agra, Bareilly and Lucknow will be observed, and the low position of the ratios of Belgam, Colaba, Aden, Fort William, Fort Dufferin, Wellington and Rangoon. The contrast between the 1899 ratios of Chakrata and of Mandalay is also striking. The reasons given by medical officers for the prevalence of enteric fever in, or the absence of enteric fever from, certain stations, including Chakrata and Mandalay, have been quoted above.

Enteric fever in regiments.—In regiments the admission and death-rates were, as in the two preceding years, highest in the cavalry; and next to them the artillery suffered most. The 47th Battery, Royal Field Artillery, was the only body of men that had an admission ratio over 100 per 1,000 and a death ratio over 40 per mille: in the 42nd Field Battery, though the admission was still higher, the death-rate was low. The 3rd Hussars had the highest cavalry admission ratio; and in the infantry the highest ratios were those of the 1st Royal Fusiliers, the 1st Northamptonshire Regiment, the 2nd Gordon Highlanders and the 2nd Welsh Regiment.

Enteric fever and age. Enteric fever and length of residence in India.—The general results of the relation of mortality from enteric fever to age and length of residence in India confirm those of former years; the relative liability to death from enteric was greatest in the age period 20–25 and in the first year of residence. The result of the relation of *admission* from enteric fever to age and length of residence in India is the same as that for mortality.

Enteric Fever and Season.—In the period 1889-98 as a whole the chief enteric months were April, May and August, and the months of least prevalence were January and February:—

Years.*	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.	Ratio per 1,000.
1889–98	754	641	1,034	1,982	2,243	1,615	1,716	1,986	1,684	1,060	1,037	1,224	16,976	24·6
1898 ...	201	165	164	332	400	219	197	238	163	124	171	124	2,498	36·9
1899 ...	111	44	84	246	229	123	96	138	111	59	·71	80	1,392	20·6

* The warning given at the end of the table of contents of the Annual Returns as to the months not being calendar months applies here also, except as regards the months of 1899.

In 1899 the greatest prevalence of enteric fever was in April, May and August; of simple continued fever in May, July and August; of remittent fever in May and August. Of the larger groups Gangetic Plain had maxima in January, April, August, and December; Upper Sub-Himalaya in January, April and December; Indus Valley in May and December; Central India in January, April, August and December; the Deccan in January, June and August; and the Hill Stations in April and September. There seems to be here some indication of a general seasonal influence.

Plague.—In the European army of India there occurred 7 cases of plague, with 2 deaths, against 9 and 2 in the previous year :—

	Admissions.	Deaths.
Poona	2	1
Kirkee	2	...
Ahmednagar	2	...
Deolali	1	1
	7	2

Besides these, 2 officers, 3 women and 4 children were attacked; one of the officers and the women and 2 children at Kirkee, the other officer at Poona, and the other children at Belgam and Deolali. In no case was the exact mode of acquisition traced, though, of course, the disease was present among the native population. It is not mentioned whether any of the patients had been on plague duty.

Scarlatina. Rubella.—Scarlatina gave 83 cases with 6 deaths, against 12 cases without death. Quetta had 25 cases with 1 death, and Kasauli 19 cases with 1 death. Of the remaining 17 stations affected, one had 9 cases, one 6, one 3, six 2, eight 1; and there was also 1 case among troops on the march. No station had more than 1 death. The Kasauli medical officer says that the disease was imported from Umballa, and in the Umballa report it is stated that all the cases there occurred in a draft from a hired transport in which cases had occurred. Eight other medical officers derive the disease from a transport with more or less certainty; and perhaps it was one and the same transport, the "Simla," which originated all or nearly all the Indian cases of 1899. At Poona the source of the disease could not be discovered, but the regiment which occupied the barracks in the preceding year had had cases. At Mooltan the first man attacked was a recruit from Dublin, and the first at Quetta was a boy who had been over a month in the country, the medical officer, however, suspecting the transport to have been the original source of the infection. The scarlatina of 1899 seems, therefore, to have been, at least for the most part, due to the importation of infection, and not to infection arising indigenously. The conclusion to be derived from a discussion in the medical papers on the subject of scarlatina in India is said to be that though it is certainly met with, especially in the hill stations, it shows very little tendency to spread, and quickly dies out, and that it sometimes attacks a few natives in a mild form. One writer asserts that scarlatina is epidemic only in countries where cow's milk (raw ?) is used: not in Japan or China, "where there are no cows," nor in India where mothers suckle long. But the explanation is not complete as regards Europeans in India. The microbiology of the disease is again under discussion. Twenty-one cases against seven of rubella were registered, nine at Mandalay, and the remainder at four other stations and on the line of march. Three of these stations returned also cases of scarlatina. There were no deaths from rubella. Some progress has been made in England in the differential diagnosis of rubella from the diseases which it most resembles, one class of cases being split off from rubella, and placed between it and scarlatina, and in Germany the necessity of distinguishing between true rubella and *erythema infectiosum* has been insisted upon.

Tubercle of the Lungs.—The admission rate from tubercle of the lungs rose from 3·0 to 3·1, while the death-rate fell from 0·58 to 0·56. The tables on pages 41 and 43 show that in 1899 the Bombay Command and the Burma Coast and Western Coast groups had the highest admission ratios. The annual reports for the stations where tubercle occurred in greatest proportion throw no light on the subject. The 16 cases returned as non-tubercular phthisis should probably be added to tubercle of the lungs. The identification of the tubercle bacillus is no longer so simple a matter as it once appeared, owing to the discovery of other acid-fast bacilli. Klein also has shown that young tubercle bacilli are sometimes not acid-fast. At the same time, by an improved technique, the tubercle bacillus can now be recovered from the fæces.

Respiratory Diseases.—Respiratory disease as a whole was much the same as in the preceding year :—

Period.	Respiratory Diseases.		Pneumonia.	
	Admissions per 1,000.	Deaths per 1,000.	Admissions per 1,000.	Deaths per 1,000.
1889–98	33	·80	4	·63
1898	29	·77	3	·61
1899	29	·75	5	·66

Of the commands, the Punjab had, as usual, the highest death-rate. As to groups, the greatest prevalence, excluding the convalescent depôts. was, as usual, in the Indus Valley. Mild bronchitis was the principal non-pneumonic affection.

Both the admission and the death-rate from pneumonia rose. Most of the cases occurred, as usual, in the north-west and in the cold weather. The five men who died at Peshawar were all more or less debilitated by previous attacks of ague, and in each case the fatal illness developed after the man's participation in the fatigues of route-marching. The medical officer suspects dust as being concerned in the causation.

Dysentery and Diarrhœa.—The admission and death rates from dysentery and from diarrhœa fell very considerably below the ratios of the previous year and those of the decennium :—

Period.	Dysentery.		Diarrhœa.	
	Admissions per 1,000.	Deaths per 1,000.	Admissions per 1,000.	Deaths per 1,000.
1889–98	30	·88	27	·07
1898	30	·78	27	·04
1899	25	·65	18	...

Dysentery was most prevalent, as usual, in the Bengal Command and in the Bengal-Orissa group. The same group and command had the highest percentage of dysentery in total cases, as may be seen in the tables on pages 41 and 43. It is usual for Bengal-Orissa to have a high dysentery ratio. The maximum month was August, and the maximum quarter July-September : the minimum month, February, and the minimum quarter, January-March. Barrackpore, Poonamallee, Dum Dum, Solon, Aden and Jubbulpore had very high ratios, especially the first three. The medical officer at Barrackpore is inclined to think that insufficient drainage is the cause of the prevalence of dysentery at that station, and that an extension of the present system would diminish it. He also notes that in spite of precautions taken for disinfecting the stools. two men admitted for other diseases apparently contracted dysentery in hospital. At Dum Dum most cases were admitted when the weather was exceedingly hot and damp. At Aden the cause was supposed to be chills contracted at the change of seasons.

In the Philippines the American Commission (Flexner, etc.) isolated a bacillus belonging to the enteric group, and considered to be probably identical with that discovered in Japan by Shiga. This bacillus reacted with the serum of dysentery patients, but not with enteric serum. The question of the causative relation of the *amœba coli* to certain forms of dysentery, those which from the beginning are subacute or chronic, is still undecided ; but there is no doubt that there are plenty of non-amœbic cases, and Flexner's bacillus was found in acute cases or in cases which were originally acute.

Hepatitis.—The admission and death-rate from hepatitis, including abscess of the liver, fell from 21 and 1·59 respectively in 1898 to 19 and 1·26 in 1899.

Venereal Diseases.—From venereal disease the admission rate for India was 313·4, against 362·9 in the previous year and 485·7 in 1897. In other words, in 1899 for every 1,000 men there were nearly 50 fewer admissions to hospital for venereal

disease than in 1898. All the commands shared in the decrease, but it was greatest in Bombay and Bengal. In 1899 there were 1,851·31 (against 2,201·81) men constantly sick in hospital from venereal disease—equivalent to about two regiments. The out-patient system reduces the number of men constantly sick in hospital. Excluding from the calculation men at Lundi Kotal, for whom the necessary data are not available, the average stay of a case of venereal disease in hospital was 31·89 days (against 33·31); and the total loss of service was about 675,728 days (against 803,661). There were 14 deaths (0·21 per 1,000 of strength), and 442 invalidings (6·53 per 1,000) directly due to venereal disease—against 17, or 0·25 per 1,000 of strength, and 569, or 8·40 per 1,000.

The only station ratio over 700 per 1,000 of strength was that of Saugor. The greatest increases of ratio (increases of more than 100 per 1,000) were at Ramandrug (strength only 16), Solon, Deolali, Fort Dufferin, Dinapore, and Shahjahanpur. In 26 stations (against 39) the admission-rate from secondary syphilis was over 100 per 1,000 of strength; the highest ratios, excluding stations of very low strength, being those of Deolali, Poonamallee and Chaubuttia; and in 18 other stations (against 47) it was over 75 per 1,000.

For India the ratio of primary syphilis *plus* soft chancre diminished by 24·5 per 1,000 of strength, the ratio of secondary syphilis by 15·2 per 1,000, and the ratio of gonorrhœa by 9·8 per 1,000; the percentages of possible reduction being respectively 16·9, 17·5 and 7·5. In 1899 the Madras Command had the highest ratio for primary syphilis *plus* soft chancre, and, as usual, for secondary syphilis; the Bengal Command had the highest ratio for gonorrhœa. To show how individual opinion influences statistics, and to justify to some extent the lumping together of primary syphilis and soft chancre in this paragraph, it may be stated that the medical officer at Belgam favours placing all primary venereal sores under soft chancre to begin with, while the medical officer of Meiktila would put them all provisionally under primary syphilis.

For increase of venereal disease causes assigned were re-admissions, garrison being at full strength, greater care in detection, influx of diseased women from another station, influx of diseased men from another station. Some of the explanations of decrease of venereal disease given were,—stricter action under the Contonment Act, the out-patient system, the more continuous and thorough treatment of patients (reducing re-admissions), the effect of cantonment hospitals, constant examinations and surprise inspections of the men; efforts of officers by means of warnings, lectures, &c.; improved discipline, moral tone and sobriety; diminution in the number of prostitutes, departure of diseased women, measures adopted to keep women away, encouragement of games and athletics, not allowing men to go to the bazaar, unless properly dressed (the trouble deters them); placing bazaars, brothels and liquor shops out of bounds; the emptying out of the bazaar in plague time; men being below par, and not inclined for venery; departure of women for the hills in summer, presence of an energetic cantonment magistrate, the provision of lotions and towels for the men in bazaars and barracks, hospital stoppages.

The following table shows the admission-rate for venereal disease as far back as the records for India as a whole permit. The heading "primary syphilis" includes the soft sore throughout:—

Year.	Primary Syphilis.	Secondary Syphilis.	Total Venereal Diseases.	Year.	Primary Syphilis.	Secondary Syphilis.	Total Venereal Diseases.
1872	61·2	22·4	179·0	1886	157·9	33·3	389·5
1873	53·4	20·4	166·7	1887	142·1	29·4	361·2
1874	68·3	25·2	192·7	1888	142·1	32·4	370·6
1875	67·1	25·1	205·1	1889	225·1	51·2	481·5
1876	59·8	23·9	189·9	1890	220·7	66·3	503·5
1877	65·2	22·1	208·5	1891	159·2	60·0	400·7
1878	95·3	22·0	271·3	1892	161·1	57·8	409·9
1879	79·2	24·5	234·8	1893	213·6	61·6	466·0
1880	87·9	23·1	249·7	1894	248·1	74·6	511·4
1881	92·0	23·1	260·5	1895	239·0	84·9	522·3
1882	87·6	23·2	265·2	1896	226·4	97·7	511·6
1883	87·2	23·5	270·3	1897	201·7	101·9	485·7
1884	90·2	24·4	293·9	1898	145·0	87·1	362·9
1885	122·1	28·7	342·7	1899	120·5	71·9	313·4

The decrease in the total ratio continued, and the ratio of 1899 was the lowest since 1884. The secondary syphilis ratio also fell again.

Invaliding.—In the whole army of India 2,142 men were invalided, or 31·64 per 1,000 of strength, against 2,580 and 38·09 in the preceding year, the decrease being greatly due to the smaller number of men invalided for ague. The ratio for the decennium 1889–98 was 27·50. The proportion of invalids to strength was lowest in the Punjab Command, and highest, as before, in the Madras Command. Thirty-one per cent. of the total number invalided were sent home as unfit for further service. The case of each soldier sent home is, however, reconsidered in England by a medical board; so that the Indian figures do not show the real final disposal of invalids.

—	1895.	1896.	1897.	1898.	1899.
India	33	39	34	28	31

Invaliding according to age and Indian service.—The percentage of men who were invalided while under 25 years of age to the whole number invalided was 59, against 62 in 1898. Of the total number of men invalided, 38 per cent. were of less than two years' service, and 81 per cent. were of less than five years' service.

Invaliding from venereal disease was most frequent between the ages of 20 and 30, and especially between 20 and 25; and, although it was most frequent in the second year of service, the frequency up to five years' service was all but uniform.

Officers.—The vital statistics of officers show that the death-rate for the British army was 8·81, and that for the Indian army 7·36, both, especially the former, much lower than in the preceding year. The number of deaths from enteric fever was less than in 1898 among both classes of officers. Enteric fever caused, as usual, more deaths among the British than among the Indian officers. Possible reasons for this difference were mentioned in last report. The constantly sick, admission and death-rates were lower than for men, but the invaliding-rate higher. The admission-rates from ague, tubercle of the lungs, and venereal diseases were lower than among the men; but the death-rates from enteric fever and hepatic abscess were higher. The chief causes of admission among officers were ague and simple continued fever; and, while the admission-rates from enteric fever and ague were lessened, the admission-rates from influenza, respiratory diseases and hepatic abscess were raised. Enteric fever was the chief cause of death, but the ratio was lower than in the previous year.

There were no cases of cholera. The greatest numbers of cases of enteric fever at individual stations were four each at Lucknow, Mhow and Poona. No special explanations are given as to the occurrence of the disease among officers. The medical officer at Quetta states that two of the young officers who had been once inoculated contracted the disease, both having been unduly exposed to the sun's rays and to great fatigue; but the attack was mild in both cases, and evidently modified by the inoculation. The following note from Solon illustrates the need for caution in the use of serum diagnosis:—

An officer had two admissions from remittent fever, having previously suffered severely from malaria. Two days after his second admission I sent a specimen of his blood to Mr. Hankin, who replied that it reacted strongly to the Widal test. In the meantime the patient's temperature had dropped to normal; so, at Mr. Hankin's request, I forwarded a second specimen. This did not react. Mr. Hankin explained that the hot weather had injured the serum, and that the second result was the correct one.

Women.—The health of the women was considerably better in 1899 than in 1898, and in the table all the ratios of 1899 are lower than those of the decennium:—

Period.	Average annual strength.	Admission-rate per 1,000.	Constantly-sick rate per 1,000.	Death-rate per 1,000.
1889–98	31,595	807·7	34·5	16·46
1898	3,118	772·9	37·9	16·04
1899	3,093	670·2	33·1	14·55

The chief causes of admission were debility, ague, and the diseases peculiar to women. Among the diseases which caused increased admission were small-pox, pneumonia, dysentery, puerperal affections, and the other diseases peculiar to women; while from enteric fever, simple continued fever, malarial fevers, influenza, and debility admission was lessened. Debility caused about 38 per cent. of the total sickness, and ague 17 per cent.

The chief causes of death were enteric fever and puerperal affections. Among the diseases which gave increased mortality were malarial fevers, respiratory diseases, and bowel-complaints; but mortality from enteric fever, small-pox, tubercle of the lungs, and puerperal affections was diminished. Enteric fever caused nearly 13 per cent. of the total deaths, and puerperal diseases over 13 per cent.

There were no cases of cholera; and Lucknow was the only station where more than two cases of enteric fever occurred. No special explanation of the origin of cases among women is given by medical officers.

Children.—That the health of the children was somewhat better than in 1898, and that only the constantly-sick ratio of 1899 was greater than the corresponding ratio of the decennium, may be seen from the following table:—

Period.	Average annual strength.	Admission-rate per 1,000	Constantly sick rate per 1,000.	Death-rate per 1,000.
1889–98	57,768	575·2	24·4	45·58
1898	5,592	606·6	28·8	41·13
1899	5,500	527·1	27·2	41·09

The chief causes of admission were ague, respiratory diseases, and measles. Among the diseases with raised admission-rates were small-pox, measles, influenza, and tubercle; while admission from cholera, whooping cough, enteric fever, malarial fevers, simple continued fever, respiratory diseases, bowel complaints, and affections of the eye was lessened. Ague caused 17 per cent. of the total sickness, respiratory diseases nearly 13 per cent., and measles over 11 per cent.

The chief causes of death were respiratory diseases, diarrhœa, debility (including immaturity at birth), teething and convulsions. Among the diseases from which there was increased mortality were respiratory diseases, debility, teething, ague and diphtheria. Mortality from remittent fever, simple continued fever, bowel complaints, tubercular diseases, convulsions, and enteric fever was lowered. Respiratory diseases caused 16 per cent. of the total deaths, diarrhœa 13 per cent., debility 12 per cent., teething 10 per cent., and convulsions 9 per cent.

There was no cholera. Campbellpur, Nasirabad and Kirkee were the only stations which registered more than two cases of enteric fever—three each. Thirteen cases of scarlatina were reported: four at Quetta, two at Kasauli, two at Bangalore, and one at each of 10 other stations. All that is known as to the origin of the disease has been mentioned in page 57. Rawalpindi, Kamptee, Mhow and Ranikhet had the largest numbers of cases of measles. At Ranikhet the disease is stated to have been imported from Bareilly, at Jhansi and Mooltan to have been contracted from the children of the railway employés, and at Cherat and Kamptee to have been derived from natives.

Native Troops.

Sickness and mortality in 1899 :—The health of the Native troops was better than in the preceding year, as shown in the following table :—

Year.	Average strength.	Ratio per 1,000. Admissions into hospital.	Constantly sick.	Deaths from Cholera.	Remittent Fever.	Pneumonia.	Dysentery.	All causes.	Mortality, including absent deaths.
1889–98 ...	128,106	917	33	1·00	1·31	3·19	·68	12·70	17·40
1898	126,036	816	33	·33	1·08	3·77	·49	11·07	13·33
1899	128,529	705	28	·53	1·17	3·86	·37	10·70	14·50

The chief cause of admission was ague. Among the diseases with raised admission-rates were influenza, cholera, and small-pox. Among those with lessened rates were enteric fever, malarial fevers, simple continued fever, tubercle of the lungs, respiratory diseases, bowel complaints, scurvy, and venercal diseases. Ague caused 37 per cent. of the total admissions.

The chief causes of death were pneumonia and remittent fever. Among the diseases which caused increased mortality were small-pox, cholera, malarial and simple continued fevers, circulatory diseases, tubercle of the lungs, respiratory diseases, and debility. Among those from which mortality was lessened were enteric fever, bowel complaints, and hepatic abscess. Pneumonia caused 36 per cent. of the total deaths, and remittent fever 11 per cent.

The total number invalided for discharge was 1,618, and the chief causes of invaliding were debility, rheumatism, and venereal diseases.

If the following table be compared with that on page 41 it will be seen that the Native soldier suffered less from enteric fever, simple continued fever, diarrhœa, hepatitic affections, and venereal diseases ; and more from influenza, cholera, small-pox, ague, remittent fever, tubercle of the lungs, respiratory diseases, especially pneumonia, and dysentery, than his European comrade. He also suffered more from scurvy. These relations are usual, except with regard to tubercle of the lungs.

* For complete detail of diseases *see* Table

Commands.—Of the commands the Punjab was the most unhealthy, but it was more healthy than in the previous year. The highest ratios of mortality from cholera, ague, and dysentery were in Bengal; the highest from remittent fever, tubercle of the lungs, and pneumonia in the Punjab; the highest from small-pox, enteric fever, and respiratory diseases other than pneumonia, in Bombay; and the highest from debility in Madras.

Field Forces.—The small Mishmi Field Force was the only body of men on active service in 1899.

Geographical Groups.—The table which follows shows that for the decennium the highest constantly-sick-ratios were those of Assam, Burma Inland, and then those of Bengal-Orissa and the Hills; and the lowest those of Western Coast, Central India, Deccan, and Southern India. The highest mortalities for the decennium from cholera and from respiratory diseases were respectively in Assam and in the Indus Valley.

		Ratio per 1,000 of Strength.											
		I.	II.	III.	IV.	V.	VI.	VII.	VIII.	IX.	X.	XI.	XII.	
		Burma Coast and Bay Islands.	Burma Inland.	Assam.	Bengal and Orissa.	Gangetic Plain and Chutia Nagpur.	Upper Sub-Himalaya.	N. W. Frontier, Indus Valley, and North-Western Rajputana.	South-Eastern Rajputana, Central India, and Gujarat.	Deccan.	Western Coast.	Southern India.	Hill Stations.	India.
1889–1898.	Constantly-sick-rate...	38·7	53·1	59·8	45·4	28·4	30·9	38·6	27·4	27·7	26·6	27·8	42·2	33·1

1898.	Constantly-sick-rate...	25·9	35·7	40·3	39·9	33·5	32·4	39·0	26·3	27·1	36·3	33·4	44·5	32·9
	Death-rates from—													
	Cholera	—	—	8·40	·34	·18	·22	—	—	—	—	1·77	·11	·33
	Respiratory diseases	·72	·92	3·23	1·37	1·78	5·06	9·62	2·83	2·01	1·44	2·15	5·65	4·13
1899.	Constantly-sick-rate...	36·2	38·2	42·7	42·2	26·3	24·4	31·5	22·1	22·3	30·0	32·7	38·9	27·7
	Death-rates from—													
	Cholera	—	—	—	—	—	1·09	—	—	·10	—	·99	·05	·53
	Respiratory diseases	—	·94	—	1·74	2·60	3·54	8·97	2·80	3·14	3·02	1·86	7·42	4·23

In the following table it may be seen that Burma Coast had the highest admission ratios from simple continued fever and venereal diseases, and the lowest from respiratory disease other than pneumonia; Burma Inland the lowest from pneumonia; Assam the highest from influenza, respiratory diseases other than pneumonia, dysentery, congestion of the liver, and scurvy; Bengal-Orissa the highest from ague; Upper Sub-Himalaya the highest from cholera; Indus Valley the highest from small-pox, remittent fever, and pneumonia; Western Coast the highest from diarrhœa, and the lowest from ague: Southern India the highest from abscess of the liver and the lowest from dysentery; and the Hill Stations the highest from tubercle of the lungs. The highest constantly-sick-rate was in Assam, the highest admission rate in Bengal-Orissa, and the highest death-rate in the Hill Stations.

* Including Group Extra-India.

Stations.—Of the large stations throughout India with a strength of not less than 1,000, the following returned the highest death-rates:—Edwardesabad 28·04, Belgam 22·85, Peshawar 18·55, Mardan 17·87, and Dera Ismail Khan 17·21. Edwardesabad was in the list also in 1898, but its statistics have improved since then. The principal cause of death at all those stations was pneumonia.

Regiments.—The most unhealthy corps were the 4th Field Battery, Hyderabad Contingent, the 42nd Gurkha Rifles, the 5th Bengal Infantry, the 5th Bombay Cavalry, the 5th Punjab Infantry, and the 17th Bombay Infantry.

Principal Diseases: Influenza.—Attention having been directed to the health statistics of India, of the commands, of the geographical groups, of stations, and of regiments, it will be convenient now to consider some of the chief diseases. Influenza increased considerably, this being the first year to break the regular alternation shown in the table. The geographical groups affected both in 1898 and 1899 were II, V, VI, VII, VIII, IX, XII; III and X were newly affected in 1899; I, IV, and XI were attacked in 1898, but not in 1899. In proportion to strength the Assam group was most severely affected, and next to it the Hill Stations and the Indus Valley. The following shows its monthly progress since its beginning in 1890. The maximum month varied from year to year, but over the period as a whole most cases occurred in April and March, and fewest in October and September:—

Years.	Number of Admissions into Hospital in each Month.												Total.	Admitted per 1,000 of Strength.	Died per 1,000 of Strength.
	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.			
1890 ...	1	8	2,460	5,118	492	82	55	—	—	—	1	—	8,217	64·3	·41
1891 ...	—	—	1	—	105	259	123	106	51	22	17	215	899	7·0	·09
1892 ...	681	371	511	149	40	5	5	7	—	1	7	18	1,795	14·1	·15

1899 ...	7	145	149	65	655	210	256	61	6	5	18	9	1,586	12·3	·16
Total	1,461	1,330	4,248	6,139	1,926	719	569	295	173	165	269	1,163	18,457	14·4	·16

The greatest number of cases occurred in the Khyber Force, and at Peshawar, Wana, and Bakloh. In the Khyber and at Wana the disease was confined to two adjoining months of the year, at Peshawar to three; but at Bakloh it spread over four. In the Khyber Force the disease was mild, and had some resemblance to dengue. The following table shows that in 1899 the Native troops had, as usual, a higher ratio than the European troops, but a lower ratio than the prisoners:—

Years.	Per 1,000 of Average Strength.											
	Influenza.						Pneumonia.					
	European Troops.		Native Troops.		Prisoners.		European Troops.		Native Troops.		Prisoners.	
	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.
1890	33·4	·03	64·3	·41	78·6	·67	4·6	·90	16·7	3·96	18·5	5·71

1896	11·5	·11	10·7	·30	37·6	·60	5·2	·64	15·3	3·14	19·1	4·34
1897	4·0	·01	5·4	·04	8·4	·21	3·4	·60	13·0	2·73	15·6	4·24
1898	8·3	·01	8·3	·03	21·0	·33	3·3	·61	16·5	3·77	15·8	3·94
1899	10·0	·01	12·3	·10	14·7	·18	5·1	·66	16·6	3·86	14·4	3·34

It shows also the relations of the pneumonia death-rate year by year to the admission rate from influenza, though, of course, the presence or absence of influenza is not the only circumstance which influences the pneumonia death-rate. The cases were mostly described as having been of a mild type, but 13 deaths were returned as against four in the preceding year. There were, however, not more than three deaths at any one station.

The 37th Dogras, the 5th Punjab Infantry, and the 2nd Battalion of the 4th Gurkha Rifles were the regiments which suffered most.

Cholera.—There were 126 cases of cholera with 68 deaths, against 48 with 42 in the preceding year. The admission rate was 1·0 against 0·3, and the death-rate 0·53 against 0·33. The only months quite free from the disease were May and December; but the maximum quarter was August–October, and the maximum month August. The 42nd Gurkha Rifles and the 17th Bengal Cavalry suffered the most severely, and after them the 40th Pathans and the 4th Madras Infantry. The second and third of these were quartered at Meean Meer, and it is said that the infantry was probably infected by the cavalry through the medium of water. With the Gurkhas the disease broke out on board a steamer on the voyage from Gauhati. The disease was prevalent at Trichinopoly at the time the 4th Madras Infantry became affected.

Small-pox.—There were 46 cases of small-pox with 2 deaths, against 26 with 1 in the preceding year. The admission rate was 0·4 per 1,000 against 0·2, and the death-rate 0·02 against 0·01. In the Frontier and Indus Valley group the cases (23) bore the highest proportion to strength. Peshawar had 15 cases, and 10 of them occurred in the 37th Dogras. The medical officer of the regiment says :—

> The disease has been prevalent in all parts of Peshawar during the last six months of the year. In no case did two cases occur in the same company except after a long interval, and in no case could any connexion be traced between any case and any other case which had occurred previously in the regiment. The source of infection appeared to be always outside the regiment. The one exception was a man who was badly marked with small-pox, and was selected to act as sick attendant in the small-pox hospital. He contracted the disease a second time. One hundred and sixteen men were vaccinated during the year, but in almost all cases they had good marks of previous vaccination. Very few recruits have no marks of either small-pox or vaccination on enlistment.

Ague, Remittent Fever, Simple Continued Fever.—To ague was due nearly 37 per cent. of the sickness of the Native army. To the fact that the year over a great part of India was a dry one is probably due the reduction of the admission ratio from 335 to 260. Bengal-Orissa was by far the most malarious group, and in that part of India the monsoon rainfall was in excess. The most malarious month was October, and the least malarious April. The 12th and 4th Bengal Infantry were quartered at Calcutta in the Bengal-Orissa group, and it is stated that some of the villages in that part of the country were being deserted on account of malaria. The 1st Bengal Infantry, which next to the 12th suffered most, was in the Mauritius, where the *anopheles* was found.

Remittent fever caused 11 per cent. of the total deaths, and prevailed most in August and least in February. The admission rate fell from 20 to 17 per 1,000, but the death-rate rose from 1·08 to 1·17. The 36th Sikhs, the 27th Punjab Infantry, and the 1st Punjab Infantry had the greatest number of cases. The prophylactic issue of quinine appears to be a measure frequently employed, but in 1899, as in former years, opinions as to the results varied. It is important to begin the issue early enough.

The proportion of cases returned as simple continued fever is much lower in the Native army than in the European; perhaps because the Native soldier is not liable to enteric fever, even in a mild form, because he is not so easily affected by the heat, because his ingestion-habits are more regular, and because the tendency in the Native army is to call mild fevers ague. The highest numbers of cases were returned by the 28th Madras Infantry and the 16th Bengal Infantry. The admission-ratio fell in 1899.

Enteric Fever.—The ratio of admission from enteric fever in the Native army in 1899 was 0·1 per 1,000 of strength, and the death-rate 0·02, against 0·3 and 0·13 in the previous year. The corresponding ratios for the 22-year period 1877–98 are 0·2 and 0·09. The following table shows that the ratios for European troops are very unlike those for Native troops and prisoners :—

—	1877–87.		1888–98.		1877–98.		1899.	
	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.
European troops	9·3	3·21	23·6	6·29	17·0	4·88	20·6	5·14
Native troops ...	·2	.11	·2	·08	·2	·09	·1	·02
Jail population	·2	·10	·3	·11	·2	·10	·2	·11

Again the death ratio for ague, remittent fever, simple continued fever, and enteric fever, combined, for European troops was 5·59, for Native troops only 1·91, or as 3·1; which shows that the paucity of enteric fever in the returns of the Native army is not due to its being registered under some other fever-heading. In other words, it is quite certain that in 1899, as in former years, Native soldiers and prisoners were much less liable to enteric fever than European soldiers.

In the whole Native army of India only 18 cases with 3 deaths were returned as enteric fever, as against 40 cases with 17 deaths in 1898. Only three stations had so many as 3 cases—Dehra Dun, Edwardesabad, and Kila Drosh. The 1st Battalion, 2nd Gurkha Rifles, and the 1st Punjab Infantry returned 3 cases each, the 2nd Sikhs 2 cases, and 7 other regiments 1 case each.

Plague.—In 1899 there were 76 cases of plague with 45 deaths, against 94 with 58 in 1898, and 131 with 82 in 1897.

Respiratory Diseases.—Morbidity from respiratory diseases was reduced, but mortality increased :—

Period.	Ratio per 1,000 of Strength.			
	Respiratory Diseases.		Pneumonia.	
	Admissions.	Deaths.	Admissions.	Deaths.
1889–98...	49	3·90	14	3·19
1898	45	4·13	16	3·77
1899	44	4·23	17	3·86

Respiratory diseases are the chief cause of death in the Native army, and in 1899 nearly 40 per cent. of all deaths were due to them. For respiratory diseases other than pneumonia the admission ratios were those of Assam, Burma Inland, Indus Valley, and the Hills. Non-pneumonic respiratory diseases were most frequent in the 30th Bombay Infantry and in the Queen's Own Corps of Guides. The medical officer of the latter considers that a prominent factor in the causation of pneumonia, bronchitis, and other respiratory diseases at Mardan is the amount of irrigation that goes on both within, and in the vicinity of, cantonments, by which the humidity of the air, contrasts of temperature between day and night, and liability to chills are increased.

Pneumonia.—The admission and death rates from pneumonia, as may be seen from the table given in the preceding paragraph, rose somewhat, and were above the decennial ratios. In the second table on page 65 is displayed the relation from year to year between pneumonia and influenza. In 1899 pneumonia caused 36 per cent. of the total mortality.

Dysentery, Diarrhœa.—The admission and death ratios from dysentery and from diarrhœa in 1899 were low :—

Period.	Ratio per 1,000 of Strength.			
	Dysentery.		Diarrhœa.	
	Admissions.	Deaths.	Admissions.	Deaths.
1889–98...	50·9	·69	16·4	·37
1898	44·0	·49	9·4	·20
1899	38·0	·35	7·1	·12

The highest admission ratios for dysentery were in the Bombay Command and the Assam Group, as against the Punjab Command and the Assam Group in the two years

preceding. The highest mortality was in the Bengal Command and the Bengal-Orissa Group. After Assam, dysentery was most prevalent in Burma Coast, Western Coast, and Bengal-Orissa; and it was least prevalent in Southern India. The disease was much more common in the second half of the year than in the first, the maximum month being August and the minimum February.

Venereal Diseases.—The following table is given to compare with the corresponding one for European troops on page 59 :—

Years.	Primary Syphilis.	Secondary Syphilis.	Total Venereal Diseases.	Years.	Primary Syphilis.	Secondary Syphilis.	Total Venereal Diseases.
1877	11·5	5·3	26·7	1889	16·6	6·4	38·9
1878	16·3	5·8	37·5	1890	16·0	6·9	41·1
1879	16·5	7·0	37·1	1891	13·6	6·9	37·9
1880	15·0	5·8	33·3	1892	14·1	7·9	39·6
1881	17·9	7·2	39·5	1893	13·3	9·0	36·4
1882	14·7	5·9	34·4	1894	13·8	8·2	32·3
1883	13·0	6·5	31·6	1895	13·1	7·3	31·3
1884	11·0	5·3	27·9	1896	15·5	8·9	37·2
1885	11·2	5·9	30·1	1897	16·1	9·0	40·8
1886	13·7	6·0	28·1	1898	14·3	11·5	40·0
1887	12·6	6·1	27·4	1899	11·3	9·9	34·1
1888	13·5	5·4	31·5				

The figures for India are not available for the years before 1877. Primary syphilis includes the local sore throughout. All the venereal ratios of Native troops run at a much lower level than those of European troops, and they have remained comparatively steady during the years of which the statistics are given.

Leaving the Hyderabad Contingent out of account, the lowest ratios for both European and Native troops were, as in 1898, those of the Punjab Command; while for both European and Native troops the Madras Command had the highest ratio. In all the commands the ratios of Native troops were much lower than those of European troops.

Whilst among the European troops an average strength of 67,697 gave 21,217 admissions, in the case of Native troops an average strength of 128,529 gave only 4,378 admissions. In other words, there were only 34 admissions for every 1,000 men among Native troops, against 313 for every 1,000 among European troops.

The admission rate was 5·9 per 1,000 of strength less than in 1898. There were 12 deaths and 133 invalidings *directly* due to venereal disease. In 20 stations out of 199 (against 36 out of 198) the admission rate from secondary syphilis was over 20 per 1,000 of strength and in 45 (against 44) it was over 10 per 1,000 of strength.

For India the ratio of primary syphilis *plus* soft chancre fell by 3·0 per 1,000 of strength, that of secondary syphilis by 1·6, and that of gonorrhœa by 1·3; the net result being a fall of 5·9 for all forms of venereal disease taken together, as noticed above. In 1898 the Madras Command had the highest ratio for each form of venereal disease.

Beri-beri, Strongylus Duodenalis.—All the 202 cases of beri-beri occurred in Madras regiments, especially the 2nd and 7th Infantry. The medical officer of the latter submits a report, but admits that he has not been able to throw any new light upon the etiology of the disease. The men affected in the 11th Madras Infantry were chiefly natives of the endemic area. The increased prevalence of beri-beri in the 2nd Madras Infantry is explained as due to the men having become saturated with the poison from further residence in Vizianagram. The disease prevails in the moist months of August and September, but a heavy fall of rain almost completely stops it. About a fourth of the men of the regiment have had their health undermined by their less than two years' stay

in Vizianagram. There was little mortality, and most men were eventually able to return to duty; but some of the paralytic and other symptoms were decided.

The intimate cause of beri-beri has not yet been discovered, or at least no agreement has been reached on the point; and in the meantime it is not possible to feel sure how much of the beri-beri of the Native army returns is really beri-beri and how much is malaria. So far as they have gone, the researches of Fearnside have had the effect of transferring cases from the head of beri-beri to that of malaria.

No cases of sickness or death caused by the *Strongylus duodenalis* (*Dochmius*, *Ancylostomum*) were reported.

Jails.

Sickness and Mortality in 1899.—The health of the prisoners in the jails of India was better even than in the previous year, and showed a marked improvement over that of 1897 and of the quinquennium.

Year.	Average Strength.	Ratio per 1,000.									
		Admissions into Hospital.	Constantly Sick.	Deaths from							
				Cholera.	Remittent Fever.	Dysentery.	Diarrhœa.	Respiratory Diseases.	Tubercle of the Lungs.	Anæmia and Debility.	All Causes.
1894–98*	127,569	886	36	1·47	·95	6·37	2·01	4·50	2·52	1·62	26·17
1898* ...	111,344	976	39	·13	·95	5·72	1·48	4·88	3·25	2·01	25·87
1899* ...	110,016	918	35	·56	·82	5·47	1·31	4·30	3·55	·95	23·87

The following provinces showed the lowest death-rates:—Berar and Secunderabad, Madras, the Punjab, Burma, the North-Western Provinces and Oudh, and Bengal. The provinces which were above the all-India average are the Central Provinces, Bombay, the Andamans, and Assam. The diseases which caused the greatest number of admissions to hospital were malarial fevers, dysentery, abscesses and boils, and diarrhœa; but those causing the greatest number of deaths were dysentery, tubercle of the lungs, diarrhœa, pneumonia, and other respiratory diseases. Dysentery caused nearly 23 per cent. of the total deaths, tubercle of the lungs nearly 15 per cent., and pneumonia 14 per cent.

Administrations.—The following table contrasts the health of the different jail administrations:—

—	Year.	Average Strength.	Ratio per 1,000.*									
			Admissions.	Constantly Sick.	Deaths from							
					Cholera.	Remittent Fever.	Dysentery.	Diarrhœa.	Respiratory Diseases.	Tubercle of the Lungs	Anæmia and Debility.	All Causes.

* Excluding subsidiary jails.

It will be seen that although taking India as a whole the prisoners were healthier than in the previous year, yet this result is due to the marked improvement in certain provinces only, *e.g.*, Madras, the Central Provinces, and the North-Western Provinces. On the other hand, there was a marked falling off in health in the Andamans and Assam. In the Andamans the increased mortality is seen under every heading in the above table, and especially from dysentery and tubercle of the lungs. In Assam much of the mortality increase was due to the sharp outbreak of cholera in Gauhati Jail in October, 17 deaths in 25 cases. The year 1899 was, however, a good year for cholera. In every instance, except Assam, the mortality was much less than the quinquennial average, though it was not so free from cholera as 1898. The Andamans, as usual, the Berar-Secunderabad administration, and the Punjab, were free from cholera. Indeed, for the past seven years the jails of the Punjab have been cholera-free.

The death-rates returned under the heading " remittent fever " may, speaking generally, be taken as an index of the severity of the type of malarial fever ; and there is an increase under this heading in the Andamans, Assam, Berar, and the North-Western Provinces and Oudh. All others show a decrease. How much this is due to the influence of modern views about the malarial fevers it is difficult to say. Dysentery shows the highest ratio for mortality in the Andamans, Bengal, Assam, and the North-Western Provinces ; but in the Central Provinces, Assam, and Bengal it is much less than the quinquennial average. The ratio from respiratory diseases is highest in Assam. In most of the other provinces it is distinctly less than the decennial average. Tubercle of the

lungs shows a marked increase in the Andamans, Assam, and Bengal, while it is less in Burma, the North-Western Provinces, the Central Provinces, and Madras.

Anæmia and debility is not a satisfactory diagnosis, and there is a falling off in the cases returned under this vague heading in Assam, the North-Western Provinces, the Punjab, Bombay, Berar, and the Central Provinces.

Andamans.—Last year the Senior Medical Officer commented upon the scanty vegetable supply of these islands. In 1899 he reports a great improvement in the supply. *Roselle* has been widely planted, and proved much more acceptable to north of India convicts than the tamarind formerly issued. Mangoes and limes have been extensively planted. Boiled water is used by all labouring convicts. In the dry weather several tanks dried up, and were thoroughly cleaned out. There was a great increase in the amount of malarial fever, dysentery, and anæmia cases. There was much increase in the deaths from dysentery, respiratory affections, and tubercle of the lungs. The type of malarial fevers was mild. The dysentery deaths occurred to a large extent among old and feeble chronic cases. The Senior Medical Officer attributed the almost total disappearance of scurvy to the great improvement in the vegetable diet.

Burma.—There was a slight falling off in the average annual strength, and there was but little overcrowding except for short periods. It is noted that the regulation diet was not sufficient to prevent loss of weight in men employed on the severer forms of hard labour, and extra food was issued in several instances in the form of rice (4 oz.) or *dal* (2 oz.). As noted by the Inspector-General last year, the water of Pakokku Jail and of Magwe Jail contained 70 and 100 grains of solids per gallon, yet the health is exceptionally good. The system of direct trenching of night soil was found satisfactory. Sixteen per cent. of prisoners confessed to being habitual opium smokers before admission. The Superintendent of Bhamo Jail urges that confinement in jail and deprivation of opium may have a strong predisposing effect in rendering the prisoners more liable to dysentery. The site of Moulmein Jail is radically bad, low-lying, and water-logged. The chief mortality in this jail was from tuberculosis and dysentery. The latter disease was of a bad type, and especially attacked Karens and other hill tribes.

Assam.—The average annual strength was the highest for the quinquennium. The high mortality was due to the cholera outbreak at Gauhati; apart from cholera, it was practically the same as in the previous year, in which there was only one death from cholera. In three jails there were no deaths. The Chief Commissioner comments strongly upon the terrible mortality which prevails in the jails of Assam, and attributes it to the exposure involved in extramural labour, which is very largely in vogue for prisoners in these jails. This point is now being put to the test in Assam. Another important point, however, is the frequent absences of the superintendents of the jails on sanitary and inspection tours, which are part of their duties as civil surgeons of the districts. When the medical superintendent of a jail is absent on a tour for 82 or 121 days, it is absolutely certain that he cannot exercise that close and unremitting attention to the health of prisoners that is necessary, if death-rates and sickness are to be kept at a low figure. Assam is notoriously malarious, and the death-rate for malarial fevers is highest in Assam jails (11·34). The dysentery death-rate is also high. While Assam has the highest death-rate in India, the admission rate is only fourth on the list. Where the general health of the prisoners is bad, it is generally wise to make free use of the hospital; by admitting patients early and keeping them in hospital till they are thoroughly cured many lives will be saved.

Bengal.—The year 1899 was a healthy one in Bengal, the death-rate being 23·79, or a trifle beyond that of 1898, which was the lowest on record for Bengal, the average for the past quinquennium being 32·06 per 1,000. Cholera and small-pox were practically unknown during the year, and the admission rate for malarial fevers was moderate. The dysentery admission rate remained high, but the cases were generally of a mild type. Influenza caused a small number of admissions. There was but little overcrowding, except in Mymensingh Jail. The accommodation for under-trial prisoners is very limited in several jails. The scheme for boiling and filtering water in Buxar was completed, and and the Pasteur filters worked on the whole well in the five jails supplied with them, though it is not clear that their use has in any way diminished the incidence of diseases generally considered to be water-borne. At Mymensingh dried plantain flour was used with success in the dietetic treatment of bowel-complaints. Buxar Central Prison suffered most from malarial fevers, as also in the previous year. This fever prevalence is

general all over the town of Buxar, and is said to be connected with the high level of the sub-soil water caused by the canals.

Prophylaxis by quinine was generally carefully carried out, and control experiments were instituted in three large jails. At Bhagalpur the incidence of malarial fevers and of bowel-complaints proved to be exactly equal in the gangs taking quinine and those who did not receive the drug. At Hazaribagh, however, a distinct advantage was apparent on the side of those who received the drug. The trial was only made at Buxar for one month. It is to be hoped that these valuable experiments will be continued till the question of the prophylaxis of malaria by quinine is finally settled. Tuberculosis of the lungs was much more prevalent and fatal than in former years. Pneumonia cases were less frequent. There were six cases and four deaths from cerebro-spinal fever. Dacca, Hazaribagh, and Bhagalpur Central Prisons showed remarkably low death-rates. The rates for the Alipore and Presidency Central Prisons were high on account of the number of cases of tubercle of the lungs. The open air treatment of these cases was carried out with success in Bhagalpur Jail, and should be tried at other jails. Midnapur, as usual, was not healthy; prisoners from Chaibassa especially fared badly there, and, in consequence, transfers from Chaibassa were stopped. All the jails with high mortality belonged to Eastern Bengal. In four jails there were no deaths.

North-Western Provinces and Oudh.—The sick and death-rates of the prisoners in these provinces were very satisfactory, the death-rate being only 22·25, or the second best on record for the province. All the Central Prisons show very satisfactory results; Bareilly Central Prison had a death-rate of only 8·86 per 1,000. There was a considerable decrease in the number of admissions and deaths from dysentery. The case-mortality is nevertheless high, 9 per cent., which probably in this instance points to a severe type of the disease. Isolation of dysentery cases and disinfection of stools is being more systematically carried out, but there is no unanimity of opinion as to the benefits or otherwise of isolation. The purity of the food and water still continues to receive attention. Pneumonia caused 584 admissions and 130 deaths, a case-mortality of 20 per cent.* It is, as Major Mactaggart writes, "next to dysentery the most fatal disease" in these provinces. The vast majority of superintendents are in favour of restricting the ventilation areas of sleeping barracks in the cold weather months.

Punjab.—There was a marked improvement in the health of the prisoners in the Punjab jails; contrasted with those of the previous year, both sick and death-rates were lower. As in 1897, the last half of the year was the more unhealthy. The Central Prisons were more unhealthy than the District Jails, and also more unhealthy than the Central Prisons of Bengal and the North-Western Provinces. The following figures show the steady improvement in the health of these jails in the past 20 years. In the first quinquennium the death-rate was 50·24, in the second 31·97, in the third 27·25, and in the fourth only 19·16 per 1,000. It is to be hoped the day may come when it may be reduced to 15 per 1,000. Leiutenant-Colonel Bate believes, and rightly too, that "reasonable attention given to health, far from weakening dicipline, is calculated to strengthen it." The better the general health, the more work can be got out of prisoners. The Mooltan Prison had a death-rate of 37·97, with eight deaths each from pneumonia, dysentery, and tubercle of the lungs—three essentially jail diseases. This jail is the infirmary jail, however, of the province, and received a large number of weak and sickly men. Lahore Central Prison had 50 deaths (35·29 per 1,000)—14 from tubercle, 10 from pneumonia, and 5 from dysentery. It is suggested that men transferred to Lahore Prison suffer more than the inhabitants of that district do when in the same jail. Previous to 1898, the Lahore Central Prison was usually very healthy.

Bombay.—The death-rate in the Bombay jails was only 24·72 per 1,000; very satisfactory in view of the fact that 11 jails out of 15 were considerably overcrowded throughout the year. The Bombay Common Prison (120·00), Thana (71·60) and Dharwar (45·17) showed a mortality in excess of the quinquennial average. In the Common Prison this was almost entirely due to a severe outbreak of relapsing fever—37 deaths. There were 59 deaths in Thana Jail—eight from remittent fever, nine from tubercle of the lungs, seven each from dysentery and scurvy, six from diarrhœa, and six each from pneumonia and other respiratory diseases. Out of 59 deaths, 41 took place among prisoners admitted from Nasik alone, most of whom came to jail in weak health. Malarial fevers prevailed much in Thana Jail, their probable origin being the moat

* Taking the 67 cases remaining from 1898 into account.

surrounding the jail, and the large marshy tract on three sides of the prison. This evil is stated to be irremediable. In Dharwar the mortality was raised by an outbreak of cholera which caused seven deaths. To improve the health of the Bombay prisoners, wheat was issued in lieu of bajri, etc., extra rations were given to the weakly, and cinchona alkaloids were freely administered. Potatoes were issued also thrice a week in lieu of ordinary vegetables.

Berar.—The jails of Berar were generally healthy during the year, the death-rate being only 13·32—that is, the lowest in all India. Intermittent fever caused the greatest number of admissions; tubercle, pneumonia, and dysentery, besides anæmia and debility, the greatest number of deaths.

Central Provinces.—The year is reported to have been an unusually healthy one, owing to a scanty rainfall and consequently less malaria. The death-rate per 1,000 fell from 34·63 to 24·59, and the constantly sick rate from 51·6 to 27·7. Nagpur Central Prison recorded a death-rate of only 8·66 per 1,000, a figure only a few times bettered by any large Central Prison in India. In Jubbulpore 11 deaths are stated to have been remnants of the previous famine. The high death-rate of Raipur was largely due to a severe outbreak of cerebro-spinal fever. There was only one mild outbreak of cholera in the jails of the province—six cases with one death at Bilaspur. The diet scales are liberal, but not more so than those of other provinces. Great attention was paid to the issue of antiscorbutics and good vegetables.

Coorg.—There is only one jail, at Mercara. The accommodation of the jail is 156. There was slight overcrowding for a short time only. The diet scales are liberal, and the water-supply is reported to be pure and ample. There were no less than 14 deaths, or a ratio per 1,000 of 127·27. Three deaths are returned as from "debility." The death-rate was much higher than in the previous four years. Bowel-complaints and malarial fevers prevailed. This is attributed to the famished condition of new arrivals in the jail.

Madras.—The lowness of the death-rate (16·13) is unprecedented in the annals of the Madras jails. This is attributed to the absence of any epidemic, and to the good health of those newly admitted to jail. The Central Prisons show a somewhat higher death-rate than the District Jails. The Rajamundry Central Prison showed a remarkable improvement, the death-rate falling from 123·03 per 1,000 in 1897, 193·23 in 1898, down to the very low figure of 14·29 in 1899. There was considerable overcrowding in three jails only. The reduction in the population of Rajamundry Prison was attended with the best results. There was a substantial reduction in the admissions to hospital for all forms of disease. The Inspector-General notes that the remarkably low death-rate of the year is largely to be attributed to the work of the medical officers in charge.

General Population.

General Remarks.—In this section of the reports issued year by year, the difficulties that confront the vital statistician when dealing with the figures presented in the annual reports of the Provincial Sanitary Commissioners have been repeatedly emphasized. One more year has elapsed since the census was taken, and it will be readily admitted that the figures of 1891 for an enormous and heterogeneous population like that of India must render close reasoning in respect of ratios calculated thereon a futile and well-nigh impossible task. On the one hand, there is the proverbial fecundity of the people, and, on the other, this is the land of capricious and devastating epidemics; during the inter-censal period, famine has invaded many of the most fertile and populous areas, and beyond the indirect loss of life this has involved, we have to take account of its effect in setting up currents of immigration and emigration which would vitiate the best accredited registration returns. These returns are certainly improving and Local Governments are alive to their responsibilities in this respect, but nothing approaching the actual facts can be obtained while the collecting agency in both urban and rural areas remains illiterate, and until municipal bodies recognize their obligation to enforce the bye-laws under which

registration is legally compulsory within the limits of their authority. With all these drawbacks the tendency is slowly but surely towards improvement so far as the elemental facts are concerned, the bare enumeration of births and deaths. Beyond this, when we come, for example, to the distribution of the causes of death under their various headings, we must at present be content to deal with contrasts in the gross, and the broad indications they afford, for the vast majority of natives are unattended by qualified medical men, no certificates are furnished, and friends and the reporting agency alike go no further in their discrimination of death-causes than is involved in a reference to the two great classes of "fevers" and "bowel-complaints."

In the following pages, little more is attempted than a broad survey of the outstanding features of the figures relating to births and deaths in the different provinces. These prefatory remarks will prepare the reader for general indications only of the ebb and flow of the chief vital phenomena, the resultant of many factors which are lost or obscured in the general movement; the material for refined speculation on some most interesting problems is wanting, but it is necessary to allude briefly to one or two of the more remarkable features of the figures as they stand. There is first the extraordinary contrast exhibited in the infantile mortality rates. Where registration is most defective, these rates are lowest and present the widest range. In a country where death registration by qualified medical practitioners is not required by law, where still-born children are not reported, save in the presidency cities, by any agency however defective, and where infanticide by accident or design is not associated with the moral stigma and penalty attached to it in Europe, it is only to be expected that a large proportion of the deaths of infants are entirely lost to account. In Calcutta and Bombay where registration is at its best and where, owing to the presence of plague in recent years, the causes of death have been more carefully scrutinized, we find that the numbers of still-births recorded reach the high proportions of 8·4 per cent. of the total births in the former city and of 18·7 per cent. in the latter. But the Bombay percentage cannot be taken to represent the normal relation, the prevalence of plague and other epidemic diseases,—relapsing fever, small-pox and cholera which were unusually rife in Bombay during 1899, together with the influx of a famine-striken population—have undoubtedly very largely increased the number of still-births.

It cannot be doubted that from the youthful ages of the mothers, the untoward sanitary conditions in which they live and the physical labour they are called upon to perform during pregnancy, the proportion of still-births is very high as compared with that recorded in Europe. As regards the infantile mortality, a general comparison of its relative incidence in urban and rural areas shows, as might be expected, that it is far higher in the large towns than in the country. While the mean rate in Bengal for 1899 is recorded as 184·8, that for Calcutta stands at 366·8; the rate for Lower Burma is 185·7 and that for Rangoon 357·4; the Presidency of Madras where registration leaves much to be desired and where, as the Sanitary Commissioner remarks that, "it was obvious that the death of an infant who had not managed to struggle through a year of life was often held unworthy of official recognition," the infantile mortality figure is 159·8, whereas for the city of Madras it is 275·5; in the Bombay Presidency the mean rate is 192·7, but in the city itself it rose to the enormous figure of 798·69, and although the conditions of recent years have been specially unfavourable owing to plague and scarcity and the immigration of destitute waifs, it was 461·3 prior to the advent of these troubles.

It cannot be considered that the figures recorded over the country generally adequately represent the loss of life among infants; the reasons for this have already been broadly stated and it will be evident, not only from the rates given in the body of this section under each provincial heading, but also from a perusal of the lowest rates returned by each, which are as follows:—

Lowest infantile mortality rates in districts—

Berar	196·6
Central Provinces	193·8
Punjab	156·0
North-Western Provinces and Oudh	150·6
Bengal	118·0
Burma...	102·0
Madras	96·7
Bombay	93·0
Assam...	17·8

The first five are the provinces in which the birth-rates are highest, and in the first four the mean infantile mortality rates are highest, and speaking generally it may be said that the infantile mortality figure presents a rough but approximately accurate test of the comparative adequacy of registration. Where the birth-rates are exceptionally low, we also find the most defective death-registration and it is easy to understand that deaths are more readily concealed than births, and the low birth-rate which *caeteris paribus* makes for a high infantile mortality figure is more than counterbalanced by the still more defective death-rate.

Famine and the birth-rate.—One other interesting feature of the returns for the year is the extraordinarily high birth-rate, which was general all over India ; it is not only that the figures are in the case of each provincial area notably higher than in any year of the inter-censal period, but the contrast with the low birth-rates of 1897, and, to a less extent, of 1898, renders the figures the more remarkable. Two considerations immediately arise in this connexion, *viz.*, that the comparatively low birth-rates of the two preceding years were directly or indirectly due to the prevalence of famine over wide areas and to the rise in prices of common food grains nearly everywhere ; and, second, that the phenomenally high figures for 1899 are to some extent enhanced beyond the true rates on account of the defective population figure which has not been corrected since 1891. But making full allowance for this statistical error, the enormous bound in the birth-rate disclosed by the returns for the year under review deserves more than passing allusion, if it be only by way of examining the basis for the existence of the popular idea that we see quoted as "Doubleday's well-known generalization," *viz.*, that one of the consequences of famine is to increase fertility. The question of the causes of the natural increase of a population is not a simple one ; it is confused by physiological and sociological factors of extreme complexity, and in India especially, where, owing to the periodic recurrence of scarcity, it confronts the enquirer, the data available for a critical examination are often unreliable or insufficient. It may be interesting, however, to look at the facts at our disposal, as they indicate that we need not postulate the existence of an apparently paradoxical phenomenon ; and that, so far as concerns the specific question raised in the generalization quoted, we may do well first to take account of some of the more obvious factors in action.

Briefly then, it may be stated that under normal conditions the birth-rate follows a well-defined and characteristic seasonal curve (see sub-section Bengal, page 80) ; during, and for some months subsequent to, the prevalence of scarcity from failure of the harvests we see the birth-rate fall and the normal curve modified out of recognition ; at the same time the death-rate rises to an abnormal extent, and the excess mortality falls in altogether undue proportion upon the age periods at the two ends of the scale. On the return of prosperity marked by the first good harvest, we find that the birth-rate remains abnormally low for some 10 or 11 months, when an extraordinary rise ensues which is maintained for several months at a fairly consistent level, the fluctuations of the normal curve being swamped by the high tide. But while the rise in the birth-rate is delayed for nearly a year, it is to be noted that the death-rate falls to below the normal some two or three months only after the replenishment of food stocks, and it remains consistently below the normal for a period, usually extending to a full year. Now it may be averred that the sexual instinct and the struggle for food are the two fundamental physiological forces that mould the social organism ; they both combine and separate individuals, and in them we find the basis of both the egoistic and altruistic instincts. They doubtless mutually subserve each other, but when the latter becomes sterner, the former suffers and the individual seeks to maintain life at any cost. Moreover, "the reproductive system appears to be far more susceptible than any other part of the organisation to the action of any change in the conditions of life."*

Now the physical and social conditions that promote the comparative fecundity of the Indian peoples have been well summarised as follows :—

† There is the tropical climate with its accompaniment of a low standard of requirements in the way of food and clothing, and an equality of temperature that admits of an out-door life to an extent that alone renders habitable the ordinary style of dwelling. There is the extent of arable soil, most of which yields to a comparatively simple cultivation the amount of food that suffices for the wants of the family. Strongest of all is the religious sanction, or the social influence, that contains within itself all the vitality of the popular belief, and according to which the want of a male heir leads to

* "Origin of Species."
† Bombay Census Report for 1881, page 29.

difficulties with regard to the inheritance of property, as well as to the omission of ceremonial observances of the utmost importance after death. There is, lastly, the stereotyped structure and want of elasticity inherent in the form of Indian society, which retards to an indefinite degree the development of a standard of comfort in advance of that of the preceding generation, and thus discourages the foresight which, originating in the desire of rising in the social scale, has an enduring effect on the marriage relations of the class which at once acquired it.

That the result of all these sanctions to propagate their kind is not greater than it is, is doubtless due to the condition of comparative want, at any rate to a standard of diet short of full physiological requirements, for although the birth-rate is far higher than that of England, it is to be noted that the full powers of the people are exercised in this respect, whereas, as Farr has shown, there is an immense reserve of unmarried but marriageable population in England. No less than 88 per cent. of the total number of women in India between the ages of 15 and 39 were shown to be married at the last census. While the disposable income of the people scarcely varies, the harvests vary greatly, and among people living from hand to mouth on the produce of the soil, the effect of a bad season speedily makes itself felt; with the insufficiency of food comes less resistance to disease, and beyond this the loss of a harvest cuts off the recourse to ready money in the way of loans from the local bankers. The milk cattle die in enormous numbers and the young children are the first to suffer privation, and a further drain is made upon the maternal vitality which it is unable to meet.

What happens now is that marriages are deferred; not only are the times unpropitious, but the necessary funds for the ceremonial festivities, which are regarded as essential, are not forthcoming. The able-bodied men first leave their homes in search of work in less distressed areas or on relief works, and these no doubt are often accompanied by their women, or followed by them later. There is undoubtedly enforced celibacy among a large proportion of the population and with this there is also a depression of the vital functions, affecting that of reproduction. It has been noticed that the women resorting to relief camps are rarely pregnant, that is to say, that there is marked diminution in the normal proportion of pregnant women. It is now that the birth-rate falls and that the death-rate rises, but under present conditions of railway communication and relief works, it is the very young and the old who succumb, leaving for the most part the more robust section of the population, that included in the child-bearing age-periods, severely affected by privation and with the vital functions at their lowest ebb, but surviving to resume the exercise of these on the return of favouring conditions. It may be noted that in the old days when famine desolated a province cut off from outside aid and when adequate measures of relief were not organised, the adult population suffered far more severely (Madras famine 1877), and as a consequence the birth-rate fell off markedly for a number of years, until indeed a young population reaching the child-bearing age brought about a sudden increase, a fact that bears forcibly upon the point under discussion.

With the recurrence of the first bountiful harvest, the whole course of events is reversed; the wanderers return to their homes, loans are negociable, there is an excess number of marriages, many of those deferred under stress of want being consumated; co-habitation is resumed by those temporarily separated and the sexual instinct depressed by acute privation, now resumes its imperious sway fortified by comparatively abundant food and freedom from anxiety, as also there are fewer mouths to fill, the unproductive members having largely died off. There are therefore all the conditions promoting an abnormal excess of conceptions during the few months following this resumption of the placid tenour of home life and the establishment of many new homes. If any stimulus were necessary to the production of offspring, we might find it in the great loss of young children sustained by the people during the famine and the imperative obligation to supply their places and remove the religious and social disabilities their absence entails. Not only therefore have we a larger number of effective agents for procreation in the period in question, but it is probable that the rhythmical impulse that attends all natural operations has gained in force by temporary rest and suspension, and as a result we must look for more than the normal average of conceptions and births; but these take place, as the figures prove, subsequent to the return of the first abundant harvest and all it connotes, and long after the fall in the death-rate announces a return of healthy and comparatively prosperous conditions. If we take into account the number of years to each birth per married woman at the reproductive ages, which in some countries is $2\frac{1}{2}$, we shall probably find nearer 2 in India, and if conceptions are deferred in one year, there will probably be an excess in the next to redress the balance. Farr called marriage the barometer of prosperity; this is also in a sense the case in India, as regards the indication afforded by a brisk "fall," and as a war diminishes the number of marriages by temporarily removing

many men of the procreative age-periods, so an excess of marriages naturally follows peace. And it is the same with famine, in the case of which there are considerations to be added in this country, which tend to enhance the natural results.

Thus we see that in the Central Provinces where famine conditions prevailed from the autumn of 1896 to that of 1897 the birth-rate was considerably below the normal from and including September 1896 to August 1898; that is to say until some 10 months after the first good harvest. Moreover, although the birth-rate is abnormally low throughout this period, we find it lowest of all in the last 10 months thereof, *viz.*, after the return of prosperity, but before its effects can be exhibited in the birth-rate. The birth-rate for the actual famine period was 28·5, while it was only 19·5 for the 11 months immediately following, October 1897 to August 1898, an annual rate of only 21·3 against the decennial mean (before the famine) of 37·9.

In September 1898 it was about normal, but in October, and thence on throughout the year 1899, it was consistently above the normal with little or no fluctuation until we get to the last two months, the rates for which more nearly approached the mean. The monthly death-rate, however, in great excess throughout the famine period, fell to about the mean in January 1898, and to below the mean in February where it remained throughout the whole of that year.

Again in the other province chiefly affected, *viz.* the North-Western Provinces, where famine prevailed during a similar period over a large, but not the whole, area; the birth-rate shows an extraordinary bound in August 1898, some 10 months after the first good harvest, and the excess over the normal mean is maintained consistently throughout the rest of that year and throughout 1899. The death-rate, high throughout the famine period, fell to normal in January 1898, and was consistently below the mean throughout that year.

It is true that in certain selected districts which have been severely stricken by famine, the birth-rate after recovery shows a higher proportional rise than that of others more fortunately situated, but this is exceptional and does not apply to all famine districts; moreover, these districts never show the highest birth-rates, and districts affected only indirectly by high prices and withdrawal of grain supplies share in the general rebound exhibited by the birth-rate, if not always yet often to as large an extent. It is impossible to appraise exactly all the factors at work in the case; a tide of immigration often sets in towards a distressed area owing to liberal relief works, &c., but if what has been said here on the whole subject be accepted, there will be no difficulty in understanding why the rebound in the birth-rate when it occurs should be proportionally higher in the affected tracts.

It is not therefore difficult to understand that in prosperous years following famine the death-rate will be comparatively low and the birth-rate correspondingly high, and that there will be a larger natural increase of the population than in what are called normal years. The weaklings, the old and the very young, have to a large extent died off, and this leaves a more resistant population, with fewer unproductive members to support; the life of the community is resumed under more favourable auspices, its future fortunes, under present social and economic conditions, depending chiefly on the process of the seasons.

It can be asserted with confidence that one of the chief physical factors affecting the birth-rate in India is the relative abundance and scarcity of the common food staples. This is strikingly demonstrated if the market prices of the latter in almost any area are plotted upon a scheme in association with the birth-rates of the corresponding subsequent years. A fall in prices is almost invariably followed by a rise in the birth-rate, and conversely; and although every petty fluctuation of the former may not find a corresponding expression in the latter, and although the effect may not always bear an exact proportion to the cause, yet both marked and sustained movements in prices invariably yield the results indicated. Moreover, when we distinguish the special local areas in a province which are associated with the highest and lowest birth-rates over a series of years, we generally find that the common food staples have been respectively more or less abundant. Of course social customs, *e.g.*, age at marriage, widow re-marriage, polygamy, &c., and economic conditions involving tides of emigration and immigration have a marked effect in modifying the general procession of the birth-rate, but in populations under approximately equal conditions in these and other respects, the quantity of food available appears to determine in largest measure the natural increase or decrease of the people. When, however, we come to compare different geographical and racial areas, the relation is not so obvious, and other complicating factors intervene (*see*

p. 81). As regards marriages among Hindus, which take place under religious sanction in certain propitious months, it can be said that occurring as these do chiefly from the middle of November to the middle of March and from the middle of April to the middle of July,* one would expect the highest monthly incidence of the birth-rate in the period from August to April, inclusive, while the curve should be at its lowest in May, June and July, and this indeed is the almost universal case under normal conditions.

Births.—The following statement furnishes a brief epitome of the birth statistics in 1898 and 1899, showing the numbers of the urban and rural populations under registration; the numbers of children born; the millesimal birth-rates, with the average rates of the previous five years; and the percentages of male to female births.

Birth Statistics.

Province.		Number of Municipalities and towns in which births were registered.	Number of rural circles in which births were registered.	Population under Registration. In Municipalities and towns.	Population under Registration. In Districts, excluding towns.	Population under Registration. Total.	Total number of births registered.	Ratio of births per 1,000 of population.	Highest birth-rate in any one district.	Lowest birth-rate in any one district.	Number of males born to every 100 females born.	Excess or deficiency of births compared with deaths.	Mean ratio of births per 1,000 during previous five years.

* Excluding Europeans and Eurasians. † Excluding Zamindaris of the Chhattisgarh Division.

In 1899 the highest birth-rates were registered, in the Berar 50·5 per 1,000, the Punjab 48·4, the North-Western Provinces and Oudh, 48·09, and the Central Provinces 47·35. Bengal follows with 42·96 per 1,000. The lowest rates were, as last year, those returned by Assam, 35·45, Madras 31·3, and Coorg 25·59.

Not only were the birth-rates recorded in 1899 higher in every province than those of the preceding year, but the increase, large in most instances, is in some cases quite phenomenal; for instance, in Berar it amounted to over 19 per 1,000; and in the North-Western Provinces to nearly 11 per 1,000. In the aggregate no less than 1,670,491 more births were registered all over British India in 1899, than in 1898, and the excess over the number for 1897 was actually 1,773,794. In view of the remarks with which this section is prefaced, the subject requires no further discussion; these extraordinary results must be read in the light of the restored prosperity of the people and of the low death-rate, indicating the generally higher standard of health which marked the previous

* The months of Sawan, Bhadon, Asoj and Kirtik (from middle of July to middle of November) are unpropitious for marriages.

year. In only one area, viz., in the small province of Coorg, were the recorded births less numerous than the deaths, but there are special local conditions, which will be alluded to later, to account for this.

The percentage of male to female births ranged from 109·6 in the Punjab and 108·09 in Bombay to 103·9 in Madras and 95·8 in Coorg.

Deaths.—The next statement gives details of the mortality in the different provinces in 1898 and 1899.

Death Statistics.

* Excluding Europeans and Eurasians. ‡ Excluding Zamindaris of the Chhattisgarh Division.

The highest death-rates registered were 39·9, in Berar, 35·72 in Bombay and 33·19 in the North-Western Provinces and Oudh; and the lowest were 28·0 in Coorg, 27·3 in Lower Burma and 20·9 in Madras.

As compared with the previous year, which was an extraordinarily healthy one, the death-rates in six of the provinces were higher, the most marked rise being recorded in Berar, with the large increase of 16·5 per 1,000; but in four provinces, viz., in the Punjab, Madras, Assam, and Coorg the rates were even lower than in 1898. In only two areas, namely, in Bombay and Lower Burma, were the rates higher than the quinquennial averages; in the former, the increased prevalence of plague and the failure of the autumn harvest account for the increased mortality, and in the latter most, if not the whole, of the rise may fairly be attributed to improved registration.

In every province the urban death-rates were higher than the rural, and the contrast is very marked in Bombay and Madras.

The urban rates were as in the case of the combined death-rates, higher than in 1898, save in the four provinces in which the recorded mortality decreased in the year under review, and the same remark applies to the rural death-rates.

The following table exhibits the monthly distribution of the mortality throughout the year :—

Statement showing Deaths from all causes, according to Months, in the different Provinces of India during the year 1899.

* Excluding Zamindaris.

The figures for each provincial area must of course be studied separately and in connexion with the meteorological data, but speaking generally of the mortality as a whole, it was higher in every month of the year when compared with 1898, the excess being most marked in the months of May and August. A feature of the year under review is the exceptional incidence upon the last quarter, probably attributable to the early failure of the monsoon and the sudden rise in the prices of the common food-grains and the presence of famine in several areas.

The following paragraphs contain a summary of the more important figures reported from the different provinces.

Bengal.—The total number of births registered in Bengal in 1899, was 3,053,178 or 509,477 more than in 1898, and the figures are notable as being by far the largest hitherto recorded in the sanitary history of the province. The millesimal ratio calculated on the census population of 1891, which had declined from 38·03 in 1896 to 36·94 in 1897 and to 35·79 in 1898, rose to 42·96, which is 7·33 per 1,000 higher than the mean of the quinquennium ending with 1898. Making every allowance for the error involved by the calculation of the rate on an obsolete census figure and for the effect of more complete registration, of which there is indubitable evidence, this increase is doubtless due to the return of prosperity owing to the occurrence of two good harvests in succession, together with the exceptional healthiness of the year 1898. "With the disappearance of famine which led to the breaking up of families and to the emigration of the males of the poorer classes in search of employment, there was a return of these to their homes during 1898 which happily was a year of plenty." The exceptionally high birth-rate which was a marked feature of the last four months of that year, was maintained throughout 1899, the excess over the monthly averages being greatest in the first five months.

The figures recorded for the period from September 1898 to May 1899 give a birth-rate of 35·05 per 1,000 which is at the rate of 46·7 per annum, although three of the months included are those in which the birth-rate is normally at its lowest. Further, the corresponding period of extraordinary conceptions must naturally be taken to be that from December 1897 to August 1898, and from figures given in the Sanitary Commissioner's report we find that period to have been one of extraordinary low death-rate, *viz.*, 23·07 per 1,000, against a mean of 25·94 for the eight-year period 1892–99 for the same months. There can be little doubt that the broad facts available lend support to the view that the return of large numbers of married males to their homes late in 1897 and in the early part of 1898, to find food cheap and abundant, and to enjoy a period of

exceptional immunity from disease, affords the best explanation of the phenomenal birth-rate of the year under review. At the same time the last word on a problem which has so long exercised vital statisticians has not been spoken, when it is sought to connect a high birth-rate with a corresponding low death-rate during the period of conception, and with the nature and amount of the food available for the population generally. This is a view held by the Sanitary Commissioner, who appeals to the monthly birth and death rate curves of his own province, and to the records of Punjab, the North-Western Provinces, and the Central Provinces, which have consistently held the first places as regards birth-rates, which he attributes to their "salubrious climate and comparatively nutritious dietary."

The most striking feature of the birth-rate when plotted month by month upon a scheme is the great and sudden rise in October followed by a consistently high rate in the succeeding winter months up to, and including, March but excluding February; the April–September period being one of comparative depression with the minimum in June. The death-rate curve is very similar; a considerable rise in October, reaching its summit in November and December, but still above the average till April (again excluding February), it is below the average from May to September with the minimum in June. It is manifest therefore that the curves run parallel in a notable degree, and if the birth-rates be plotted against the death-rates of the nine months antecedent, *e.g.*, the October birth-rate against the January death-rate and so on in respective sequence, we do not find that the curves are consistently farthest apart, as they should be on the view put forward.

But, on the contrary, it may safely be said that whatever be the causes which determine the fecundity of the population, and health is *cæteris paribus* admittedly one, the death-rate, as regards India, rather depends on the birth-rate than *vice versâ*. One-fourth of all deaths registered are among children under one year of age; infants are the most susceptible to all the conditions connoted by the term "seasonal influence," and the high birth-rate in the autumn and winter, the most unhealthy period, is accompanied by the deaths of enormous numbers of weaklings.

It is also doubtful whether the cause of the differences in the birth-rates, *when the different provinces are compared*, can be referred to the respective amounts and qualities of the dietaries or to the climatic conditions. The divisions of Behar, which approximate closely in these respects to the North-West Provinces, do not yield the highest birth-rates in Bengal, and in the case of the Central Provinces, cited in this connexion, we find that those areas in which the staple dietary is very similar to that of Bengal have a higher birth-rate than those which resemble the North-West Provinces in this respect. Certain marked local sociological characteristics have an influence that cannot be overlooked.

The highest district birth-rates were 53·28, 50·53 and 50·18 registered respectively in Palamau, Gaya and Hazaribagh; and the lowest were 31·99, 30·17 and 16·14 in the 24-Parganas, Hooghly and Calcutta, which held the same position on the list in the previous year. All the districts except Jalpaiguri, Rajshahi and Jessore show a considerable increase, thirty-two districts having returned a rate of over 40 per 1,000 against ten only in 1898.

The three exceptions mentioned show a trifling decline as compared with the previous year, but are well above the quinquennial mean. The causes of the low rate in the Calcutta (urban) district, and of the comparatively lower rate in urban circles generally as compared with rural circles, were fully discussed in this report for 1898. Of a total of 151 towns, all but 31 returned a higher birth-rate in 1899 than in the previous year, and in only 73 did the death-rate exceed the birth-rate.

As regards rural areas, it is noticeable that as many as 247 returned a birth-rate in excess of 45 per 1,000, against only 50, 82 and 85 in the three preceding years respectively. This is satisfactory, but at the same time it has to be recorded that in 16 instances the number of deaths exceeded that of the births. In most cases this is accounted for by an exceptionally high death-rate, but there are still a few in which registration must be at fault.

The provincial percentage of male to female births was 105, against 106 in 1898, and it varied from 117 in Hooghly to 102 in Hazaribagh, Ranchi and Palamau, and three other districts; it will be remembered that in the former area the birth-rate was at its lowest, and in the latter places at its highest.

The total number of deaths registered was 2,218,243, as compared with 1,888,468 in 1898, which was the healthiest year since 1890; the death-rate calculated on the census population rose from 26·57 to 31·21 per 1,000, but the latter figure should obviously be compared with that for the quinquennial mean ending 1898, which stands at 31·99. The result bears out the view that, judged by the death-rate, the year 1899 ranks as one of

comparative healthiness, especially when the natural increase of the population over that of the census figure is borne in mind. Although cholera is credited with 107,678 deaths during 1899, against 65,024 in 1898, the year of phenomenal immunity from this disease, yet the death-rate per 1,000 was only 1·51 as compared with 2·53 the mean ratio for the previous quinquennium.

Again, the mortality from fevers, which stood at the exceptionally low millesimal ratio of 19·97 in 1898, rose to 22·61 in 1899, but this again was 0·72 per 1,000 lower than the mean ratio for the five preceding years. The excess of the number of deaths over the mean for the decade is due almost entirely to the heavier mortality among infants, a result which the extraordinarily high birth-rate would lead one to expect, but the infantile mortality figure works out at the comparatively low rate of 184, as compared with 173 in the previous year, which stands out as the healthiest since 1890.

The death-rates from small-pox, dysentery and diarrhœa, and injuries show little variation from those recorded in the previous year, but there is an increase in the rate from "other causes" amounting to 1·31 and 1·53 per 1,000 over that of 1898, and over the mean of the previous decade, respectively. The increase under this head was more notable in the urban than in the rural areas, and must be considered too large and too sudden to be altogether referable to improved diagnosis. The prevalence of plague renders it imperative to scrutinize closely any notable increase in the number of deaths classed under this anomalous and comprehensive heading, in view of the well-known practice of concealing the real cause of deaths from plague.

The highest district death-rates were recorded in Malda, 50·75, Faridpur, 45·44, and Murshidabad, 43·0; and the lowest in Manbhum, 20·24, Sonthal Parganas, 20·15, and Singhbhum, 19·97. In the rural areas the average rate was 31·11 against 33·10 in towns, among which the rates varied from 69·18 in Puri, the well-known pilgrim resort, where cholera accounted for 33·34 per 1,000 of the total mortality, and 53·42 in Bhadreswar, where the deaths attributed to fevers and dysentry accounted for four-fifths of the total, to 12·87 in Raghunathpur, and 12·07 in Maniktala, which were also at the bottom of the list last year. Fever was extremely prevalent in the towns of Sherpur, Nator, Jangipur, English Bazar and Rampore Baolia, and this cause alone carried off 41·91, 36·90, 40·33, 33·21 and 33·91 per 1,000 of the population in these places respectively. No less than 11 rural areas returned a death-rate in excess of 60 per 1,000, and this also is attributable to the excessive mortality from fever in the Murshidabad, Darjeeling (Terai), Faridpur and Malda districts, the general health in Murshidabad and Malda being the worst ever recorded.

Among the various sects, Muhammadans had the highest death-rate, 34·92 per 1,000, which is 5·26 per 1,000 in excess of the decennial mean for that sect, and this is to be largely attributed to the fact that the Musalman population far outnumbers the Hindus in the districts just alluded to, and in some others, such as Jessore, Rajshahi, Dinajpur, Pabna and Dacca, where the mortality was at its highest. The death-rate among Hindus was 29·87, while that for Christians was 22·81, followed by 20·91 for "other classes," and 19·85 for Buddhists. These rates are higher than those returned in the previous year, save in the case of Buddhists, which shows a decline of 5·76 per 1,000, and this is attributed to the exceptional healthiness of the Chittagong district during 1899, a district where more than half the Buddhist population is located.

The seasonal incidence of mortality presented no important features of deviation from the usual curve.

Male infants died at the rate of 272·64 per 1,000 against 215·65 in 1898, and female infants at the rate of 221·01 against 170·28, but the infantile mortality figures, which are more reliable, as calculated on the registered number of births rather than on the obsolete census figures, are 194·15 and 175·05 for males and females respectively, as compared with 183·41 and 162·75 in the previous year. The rates among boys and girls of over one and under five also show a considerable increase over those of 1898, *viz.*, 45·35 and 38·93, against 37·18 and 31·23 per 1,000 respectively. As usual the male death-rates were higher than those returned for females at all age-periods, the averages being 33·33 and 29·10 for males and females respectively.

Port of Calcutta.—The number of European seamen who arrived in the port during 1899 was 19,647, the daily average population being 1,200, or 32 less than in 1898.

The total number of deaths among them was 60, equal to a death-rate of 50·0 against 22·72 per 1,000 in 1898; the death-rate is indeed the highest recorded since 1894, and 8·33 per 1,000 of the total were attributed to cholera.

Among the native floating population of the port, estimated at 25,630, there were 125 deaths reported, equal to a death-rate of 4·87 per 1,000, as compared with 4·70 per 1,000 in 1898.

Assam.—The vital statistics of the Naga Hills and the Garo Hills districts, hitherto treated separately, have been incorporated in the general statistics of the province ; there still remain certain outlying parts of these mountain areas, the estimated population of which is 426,243, in which registration still awaits introduction. Taking the province as a whole, the number of births recorded in 1899 was 179,027, against 148,956 in the previous year, and the birth-rate rose from 29·49 to 35·45 per 1,000, the highest on record. The highest district rates were returned from Goalpara (41·43), Garo Hills (41·23), Cachar (39·35), Sylhet (38·02) and Lakhimpur (37·72) ; and at the other end of the scale come Nowgong (21·01), Khasi and Jaintia Hills (21·51) and Kamrup (31·05), following the usual order which has been maintained during the past few years. There is still evidence of defective registration, especially in the Brahmaputra valley, where the recording agents are unpaid village head-men, and the figures for the districts of Kamrup and Nowgong and of several of the *Sadr* towns are particularly open to suspicion. The average percentage of male to female births fell from 107·65 to 106·03, and ranged from 133·33 in the Naga Hills to 92·38 in the Khasi and Jaintia Hills.

The total number of deaths recorded, which was 182,763 in 1898, fell to 156,595, and the rate per 1,000, from 36·17 to 31·01, or 6·49 per 1,000 below the quinquennial mean. Among the districts the highest rates were 44·86 in Darrang, 38·88 in Goalpara and 35·56 in the Garo Hills ; and the lowest were 23·58 in Kamrup, 24·96 in the Khasi and Jaintia Hills and 25·29 in Cachar. In rural areas the average death-rate was 30·87 per 1,000 against an average in the towns of 37·29, and among the latter the rates ranged from 76·79 in Tezpur (Darrang) and 62·65 in Gauhati (Kamrup) to 16·0 and 9·23 in Jowai and Shillong and in the Khasi and Jaintia Hills, respectively.

Hindus died at the rate of 27·43 per 1,000, followed by Christians (30·14) and Muhammadans (32·36) ; while "other classes," who numbered 520,161 at the census of 1891, yield the highest death-rate, 47·92. This latter figure would doubtless be largely modified if account were taken of immigration, but the enormous death-rates returned among "other classes" in Cachar (121·41) and Sibsagar (116·12) are far from satisfactory, and demand enquiry if only in the form of some attempt to estimate the true population at inter-censal periods by taking account of the annual influx of immigrants.

Male infants died at the rate of 200·28 and female infants at the rate of 175·89 per 1,000, calculated on the census figures of 1891 ; the infantile mortality rate, for both sexes combined, was 186·45, and ranged from 296·46 in Goalpara, where registration is at its best, to the absurd figure of 17·86 in the Naga Hills, and of 96·32 in Lakimpur. Boys and girls of over one and under five years are credited with death-rates of 29·52 and 27·77 respectively, and there is a decrease in the rates at all age periods corresponding to the lower general mortality. At all age periods, save 15–30, the male rates were the higher, the averages being 32·35 for males and 29·52 for females.

North-Western Provinces and Oudh.—Following on the exceptionally healthy year 1898, the chief feature of the vital statistics of the North-Western Provinces and Oudh is an extraordinary high birth-rate, with a death-rate which although in excess of the previous year was still below the quinquennial mean. The total number of births recorded in 1899 was 2,255,627 against 1,741,725 in the previous year, giving a birth-rate, the highest on record, of 41·09 as compared with 37·35 in 1898 and with 35·69 the average for the previous five years. While the districts, which under ordinary conditions exhibit the greatest fecundity, maintain their pride of place, the most astonishing increase in the birth-rate during the year under review is recorded of many of the areas which were stricken with famine in 1897 ; for example, one district, Banda, which yielded a rate of 13·76 in 1897 shows the enormous advance to 41·52 in 1899. Still it is among the western districts that as usual we find the actually highest rates ; Bulandshahr with 63·48, Etah with 61·14, Budaon with 59·24 as in previous years ; while the lowest were registered in Naini Tal, 28·07, Dehra Dun, 29·70, and Jaunpur, 36·52, and on the whole the eastern districts are marked by the tendency to return the lowest rates. In every district save two, viz., Naini Tal and Dehra Dun, births were more numerous than deaths, the excess of the former on the combined provincial rates amounting to nearly 15 per 1,000. The municipal birth-rate averaged 47·24 per 1,000 against 36·44 in 1898, with variations ranging from 67·99 in Kandhla to 11·58 in Mussoorie, where there is a large excess of adult males in the population.

The percentage of male to female births, which in 1898 was 108·05, fell to 107·43, and ranged from 120·68 in Dehra Dun to 100·40 in Garhwal.

The total number of deaths recorded was 1,556,821, or 272,502 more than in 1898, giving ratios of 33·19 and 27·38 respectively against a quinquennial mean of 34·56, a result which must be regarded as indicating a comparatively fair general standard of health, considering the large number of births and the high mortality among infants. The highest district death-rates were recorded in Mainpuri (41·93), Etah (41·75), and Farukhabad (40·69), and the lowest in Danda (21·24), Hamirpur (24·11) and Gorakhpur (25·01). The urban death-rate was 39·04 against 33·41 in 1898, and that for rural areas 32·76 against 26·94 in the previous year. In 18 out of the 104 municipalities the deaths exceeded the births in number, as compared with 31 in 1898 and 76 in 1897, which suggests a higher standard of health and more complete registration.

Among the various sects, Hindus had the highest death-rate, 33·52, followed by Muhammadans with 31·55 ; the recorded rate for Christians, 11·62, and for "other classes," 18·36, are open to suspicion, on account of the extraordinary variations in the rates returned by different districts, and probably many deaths among both classes are attributed to Hindus. The highest monthly death rates occurred in September, August, October, November and December, the incidence being earlier than usual ; the monthly birth-rates follow generally in the same order. The lowest death-rates occurred in February, March, July and January, and the lowest birth-rates in June, May, July and February.

Among male infants the death-rate was 336·13, and among females 310·10, against 227·74 and 210·46 in 1898 respectively. But the rates calculated on the number of births recorded during the year were 238·83 for boys and 231·14 for girls, or a combined infantile mortality rate of 235·13. The mortality among children between one and five years, which was 44·63 per 1,000 for boys and 44·48 for girls in 1898, rose to 56·21 and 55·01 respectively in 1899. At all the age periods, save 15 to 30 inclusive, males died at a higher rate than females, the average for the former being 33·62 per 1,000, and for the latter 32·73.

Punjab.—The number of births registered in the Punjab in 1899 was 994,001, a birth-rate of 48·4 per 1,000 on the census population of 1891. This rate is the highest recorded either in the Punjab or in any large province of India, save that for the Central Provinces in 1881, when a rate of 48·94 per 1,000 was returned. In 1898 the number of births recorded was 841,869, so that during the year under review there was an increase of 152,132, and a rise in the rate amounting to 7·4 per 1,000 ; and as compared with the quinquennial mean, the rise was 5·5 per 1,000. In the district of Jhang the extraordinary birth-rate of 69·1 per 1,000 was recorded, and this is attributed to the influx of large numbers of people in consequence of the opening of the Chenab Canal Colony ; even when an approximate calculation of the present population of the district is made to include recent immigrants, the birth-rate works out at 61·9. In 12 other districts the birth-rates ranged from 61·2 to 50·3, and this extraordinary record is attributed to the employment of the census population figure of 1891, to the general healthiness of the preceding year, and to improved registration. At the other end of the scale we find four districts only in which the birth-rate was below 40 per 1,000, *viz.*, Simla (21·7), Peshawar (30·4), and Kangra (36·4) and Hazara (36·8). In Simla the low rate is well accounted for by the abnormal sex distribution of the population, and as regards the frontier districts which invariably occupy a low place in the birth tables, there can be no doubt that registration is still defective, for the death-rates are also comparatively low, and the Pathan is recognized as being averse to notifying domestic occurrences.

The percentages of males born to females, which in 1898 was 110·4, fell to 109·6, and ranged from 122·6 in Dera Ghazi Khan to 105·4 in Simla.

The number of deaths registered in 1899 was 607,725 against 638,124 in the previous year, giving death-rates of 29·57 and 31·05 per 1,000 respectively, as compared with the quinquennial mean of 31·9. The highest rates were returned from Jhang (41·6), Karnal (35·3) and Gurgaon (35), and as regards the first, the comparatively high mortality recorded is attributed to prevalence of malarial fever due to irrigation, and to an underestimated population figure on which the ratio is calculated. The lowest death-rates were registered in Montgomery (20·3), Dera Ghazi Khan (21·7), Simla and Hazara (both 22·6) ; the rate recorded for Montgomery is suspiciously low, and the fact that the infantile mortality figure is only 183 against an average of 207 for the province is significant of defective registration, which is also recognized as a factor to be taken into account in considering the low rates recorded in the frontier districts. The average death-rate

returned by rural circles was 29·23 against 32·58 by the towns, in which rates ranged from 44·90 in Kaithal (Karnal), and 44·80 in Muzaffargarh to 12·07 in Kulachi (Dera Ismail Khan) and 13·83 in Abbottabad. The average rate for the principal towns was 34 per 1,000, as in 1898, the lowest figure recorded since 1889, and 5 per 1,000 less than the average of the previous ten years.

Among the various sects by far the highest rate, as usual, was returned against "other classes," *viz.*, 138·45, a very great rise over the figures for the previous year (79·61), but the population did not exceed 6,067 in 1891, and apart from errors due to a probable large increase, of which no account is taken in calculating the ratio, and to erroneous registration, the rate is generally enhanced by the inclusion of 921 deaths from cholera among immigrants from Bikanir, whose religion could not be ascertained. Hindus had a death-rate of 30·72, practically the same as in 1898; the rate for Muhammadans was 28·55 against 31·19 in 1898; and that for Christians 18·23 against 19·54.

The seasonal incidence of mortality presented no exceptional features, the highest death-rates were recorded in December, November and August, and the lowest in April, July, June and February.

Male infants died at the rate of 230·88 per 1,000, and females at the rate of 229·01, compared with 215·19 and 210·09 respectively in 1898. The combined infantile mortality figure, calculated on the births recorded during the year, was 207, and with the wide range from 303·7 in Simla District to 156 in Peshawar District. Children between one and five years died at the rates of 47·97 and 51·27 per 1,000, against 63·04 and 68·57 respectively in 1898. At all age periods, save those of infancy and between 40 and 60 years, the female death-rates were the higher, the averages being 28·49 per 1,000 for males and 30·82 for females; this relation of the mortality of the sexes is quite exceptional, and contrasts notably with the Bengal returns.

Central Provinces.—The main features of the vital statistics of the Central Provinces are the extraordinary birth and death rates when the figures of the last three years are compared. Excluding the Zamindaris, the figures for which have only been reported for the last two years, we find a birth-rate rising from 26·83 per 1,000 in 1897 to 29·91 in 1898 and 47·35 in 1899; a death-rate falling from 69·34 in the first year to 24·3 in the second, and rising again to 28·09 in the third year.

In 1898 the number of births recorded was 284,176, a ratio per 1,000 of 29·91, and the figures rose in 1889 to 449,895 and 47·35 per 1,000 respectively. The extraordinary upward bound exhibited by the monthly rates in September, 1898, was fully maintained throughout the year under review, and reached its acme in April and August, in each of which months over 40,000 births were recorded, equal to an annual rate of over 50 per 1,000 on the census population. It is necessary to go back to 1881, when the birth-rate returned was 48·94, to find a record of fecundity at all approaching that of 1899, which was 11·64 higher than the decennial mean, and taken along with the comparatively low death-rate, one may entertain the hope that the figures indicate a return of prosperity and a remarkable recovery from the effects of the famine of 1897.

As compared with the previous year, the increase has been fairly distributed over all the districts, the highest rates being returned from Burhanpur (60·06), Nimar (58·59) and Chindwara (54·78); and the lowest from Saugor (38·58), Hoshangabad (42·04), Balaghat (42·88) and Narsingpur (43·34). In every district there was an excess of births over deaths, the average excess for the *Khalsa* amounting to 19·26 per 1,000; the rate recorded in rural circles was 47·56 against 44·64 in the municipal towns. The percentage of male to female births was 105·29, and ranged from 111·68 in Murwara to 101·68 in Chhindwara.

The total number of registered deaths which was 230,907 in 1898 (24·30 per 1,000) rose to 266·930, a ratio of 28·09 per 1,000 in 1899, compared with 43·38 the quinquennial mean. Among the districts the highest rates registered were 46·15 in Burhanpur, 45·16 in Nimar, 33·28 in Wardha, and 32·86 in Chhindwara, and the lowest were 23·05 in Bilaspur, 23·17 in Saugor, and 23·91 in Mandla. In the rural areas the average rate was 27·53 per 1,000 as compared with 34·11 in the towns, where the death-rate ranged from 70·28 in Arung (Raipur), 62·50 in Katol (Nagpur), and 59·54 in Arvi (Warda), to 15·92 in Saugor Cantonment, 16·05 in Rajim (Raipur), and 16·29 in Rehli (Saugor).

The seasonal incidence of disease as indicated by the monthly death-rates exhibited a marked variation from the normal; the highest rates were recorded during the first six months, and the mortality curve reached its highest points in April and March, falling thereafter to July, and showing little variation throughout the rest of the year, where it maintained a line considerably below the normal. The Sanitary Commissioner throws no

light on this exceptional seasonal incidence, but it is apparently due to the abnormal mortality from "fevers" in the earlier months, with an exceptional immunity therefrom in the autumn, the latter fact being possibly associated with an abnormally light total rainfall and its early cessation.

The death-rate among Hindus was, as in the previous year, the lowest, viz., 25·46 per 1,000, Muhammadans following with 29·87, while that for "other classes," invariably the highest, was returned at 42·35.

The death-rate among infants, as calculated on the census population, was 416·94 per 1,000 for males and 350·11 for females, or nearly double the figures for 1898; but in a population that has passed through such vicissitudes during the last three years this is eminently a case where it is necessary to take the ratios on the recorded births for the year. In this way the infantile mortality rate for the province works out at 229, ranging from 294·2 in Nimar District to 193·8 in Murwara District. It is a notable fact that four districts, Saugor, Damoh, Murwara, and Nursingpur, have a combined average infantile mortality rate of under 200, moreover in these same areas the urban birth-rate exceeds the rural, both facts pointing to defective registration. Children over one and under five years of age died at the rate of 25·85 and 21·02 per 1,000 respectively, the mortality, so far as it can be judged by the figures, being slightly less than in the previous year. As is invariably the case in the Central Provinces, the male death-rate were higher at every age period, the average being 30·48, and for females 25·71 per 1,000.

Berar.—The number of births registered in Berar in 1898 was 89,414, a rate of 31·3 per 1,000, but in 1899 the enormous number of 144,034 births was registered, giving a rate per 1,000 on the census population of 50·5, the highest on record for the area, and indeed for any Indian province; moreover, it was no less than 14·5 per 1,000 in excess of the quinquennial mean. In the Akola District the rate was 54·3, and in Buldina 53·2 per 1000, while the lowest rates were 45·8 and 48·6 per 1,000 in Basim and Wun respectively. The previous year, judged by the low death-rate recorded (23·4), was exceptionally healthy, and with this was associated an abundant harvest and low prices for staple foods, and doubtless these were important factors in restoring those conditions of vitality on which fecundity depends. But there is reason to believe that the census population figure on which the rates are calculated is considerably below the actual number of the present inhabitants, which, apart from the natural increase, has probably been enhanced by immigration owing to hard times in neighbouring areas. The number of births recorded exceeded the deaths in every district, the largest excess being shown in Buldana, 15·6 per 1,000.

The average percentage of male to female births was 106·4, varying between 108·5 in Ellichpur to 105·4 in Buldana.

The number of deaths showed an equally remarkable rise, viz., from 66,806, or a ratio per 1,000 of 23·4, to 113,992, which is 39·9 per 1,000 on the census population. The registered causes of mortality show an increase under all heads, save that of "small-pox," and the increase was largest in the districts of Akola (25·7) and Ellichpur (21·3). The explanation of this remarkable rise in the death-rate as compared with the previous year is probably to be found in the prevalence of influenza, which was particularly fatal in March, April and May, and which not only accounts for the unusual seasonal incidence of the fever-mortality, but also probably explains the increase (6·8 per 1,000) in the death-rate from "other causes" over that of 1898; the excess of population over that of the census figure, and the extraordinarily high birth-rate were doubtless also factors, the former in rendering the ratio calculation fallacious, and the latter in providing a large number of infants to fall a prey to fatal disease. Akola with 50·8, and Ellichpur with 45·6, returned the highest death-rates; the lowest being attributed to Basim with 35·5, and Wun with 30·9, the latter figure being probably due to defective registration. In rural areas the average death-rate was 39·5, against 42·6 in the towns, in which the extremes registered were 55·8 per 1,000 in Shegaon (Akola) and 28·8 in Sendurjana (Amraoti).

As regards sects the highest death-rate was attributed to "other classes," 44·4 per 1,000; Hindus followed with 40·0, Muhammadans with 36·4, and Christians with 27·1 per 1,000.

Male and female infants died at the rates of 392·5 and 337·1 per 1,000 against 194·8 and 168·8 respectively in the previous year. The combined infantile mortality rate calculated on the births recorded was 231·5 in 1899, but in one district (Wun) the figure returned is only 196·6, which supports the suggestion that registration needs attention. Children between one and five years of age died at the rates of 93·2 and 81·9 per 1,000 respectively, a mortality just twice as high as that recorded in the previous

year. At all the age periods from 10 to 40 inclusive the female death-rates were higher than those of males, but below and above these ages the rates for males showed an excess ; the averages at all ages being, for males 41·0, and for females 38·8 per 1,000.

Madras.—The notable features of the vital statistics of the Madras Presidency in 1899 are, as usual, the extraordinarily low birth and death rates and the wide range of variation not only between the figures recorded for urban and rural centres taken in the sum, but also between those of the different urban and rural centres when compared *inter se.*

The total number of births recorded in 1898 was 911,742, a ratio of 27·4 per 1,000, but the figures rose to 1,048,335 and 31·3 per 1,000 in 1899, giving the highest rate ever recorded, and an advance of 2·7 per 1,000 over that of the quinquennial mean. All but five of the 22 districts share in the increase, the highest rates being 40·5 in Kistna, 40·4 in Madras and 37·2 in Vizagapatam, and the lowest were 22·3 in Madura, 26·0 in Malabar and 26·4 in Nellore. The largest increase as compared with 1898 is found in the districts affected by famine in 1897, but still it is noted that the rates recorded in these were in some cases below their normal average. In rural areas the average birth-rate was 30·9 against 35·7 per 1,000 in the towns, a relation which is exceptional and confined to this Presidency.

The percentage of male to female births was 103·9 against 104·3 in the previous year, and ranged from 107·6 in the Nilgiris to 100·1 in Anantapur.

The total number of deaths registered in 1899 was 675,094, or 24,014 fewer than in the preceding year, and the ratio per 1,000 which had fallen to 21·0 declined still further to 20·1, or 1·2 per 1,000 below the quinquennial average, the decrease being attributable to the diminished prevalence of cholera. The Sanitary Commissioner remarks that "it is hopeless to attempt, under existing circumstances of registration, to criticize the death-rates reported from districts. They may possibly sink to the almost certainly ridiculous rate of 14·4 per 1,000 in Ganjam, or rise to nearly 30 per 1,000 in South Canara, without its being possible to state definitely what are the errors of omission or commission." But it is pointed out that "there is a tendency to ignore the deaths of infants," and this is borne out by an analysis of the infantile mortality rates in different areas. For example, Vizagapatam added 13·4 per 1,000 to its birth-rate (23·8 in 1898 and 37·2 in 1899), and maintained a stationary death-rate (18·5), and yet the infantile mortality figure which was 115·4 in the former year rose merely to 117·9 in 1899 against the provincial average of 159·8. The Malabar district birth-rate rose by 7·4 per 1,000, but the death-rate fell by 2 per 1000, and the infantile mortality figure likewise fell from 101·4 to 96·7. Again, the following figures are instructive :—

——	Urban.	Rural.	Excess of Urban.
Death-rate per 1,000	29·1	19·4	52 per cent.
Infantile mortality	223·9	159·8	40 per cent.

The neglect to register the deaths of infants doubtless accounts for much of the variation in the different death-rates recorded, though town-life is more unhealthy and registration at other age periods more complete in urban circles, which is borne out by the fact that the death-rate from "other causes," which takes the leading place in the mortality figures, was no less than 17·4 per 1,000 in urban and only 9·5 per 1,000 in rural centres.

The local authorities have long recognised the necessity for measures for the improvement of registration, and one important result has been the passing of the "Registration of Births and Deaths Act," 1899, which is to be worked, at first, tentatively in selected rural areas ; this is undoubtedly a very necessary and hopeful measure.

Among the different sects the highest death-rate was registered among "other classes," 23·6 per 1,000 against 14·1 in 1898 ; Hindus followed with 20·3, Muhammadans with 18·6, and Christians with 16·3, showing little variation as compared with the previous year's figures.

The highest monthly death-rate was recorded in January (2·2) with a steady fall through February and March to the lowest figure in April (1·4) ; from May to September there was little variation (1·5 to 1·6) ; and from October came the usual steady rise, from 1·7 to 1·9 in November, and to 2·0 in December.

Male infants died at the rate of 158·0 per 1,000 of the census population at that age, and females at the rate of 131·1 ; the infantile mortality calculated on the births has already been referred to. Children between one and five years of age died at the rates of 24·2 and 22·7 for boys and girls respectively. At all age periods, save those from 10—30 inclusive, males had higher death-rates than females, the average at all periods being 20·7 per 1,000 for the former and 19·5 for the latter.

Coorg.—The feature of chief interest in the vital statistics of Coorg is the relation borne by the births to the deaths ; in all but two years in the last decade the latter have exceeded the former, and the explanation given is that more than one-third of the total population consists of immigrant coolies, who generally come without their families, and who while adding little to the births contribute largely to the death-rate. There can be no doubt that this explanation is correct to a large extent, though it is doubtful if it covers the whole of the deficit which the figures disclose. Under such circumstances, it is clear that the census figures of 1891 are not trustworthy, and the difficulty of arriving at safe conclusions is enhanced by the fact that registration is not compulsory. It has been decided to register henceforth the deaths among the immigrants separately from those of the indigenous population, and if this distinction be extended to the births, we may hope for a notable improvement in the fundamental basis of sanitary reform, especially if the proposal to enforce compulsory registration, now under consideration, be carried out.

The total number of births, which had fallen in 1898 to 2,795, a rate of 16·15 per 1,000, rose to 4,427, or 25·59 per 1,000, in 1899, which amounts to an excess of 2·43 over the average for the quinquennium. The rates in the various districts ranged from 32·53 per 1,000 in Padinalknad and 26·86 in Nanjarajpatna, to 21·07 in Yedenalknad and 22·80 in Mercara ; in only two of the five districts did the number of births exceed that of the deaths. The average birth-rate in the towns was 15·67 compared with 7·67 in 1898.

The percentage of males to females born which was 107·34 in the previous year fell unaccountably to 95·80, ranging from 106·64 in Nanjarajpatna to 86·34 in Yedenalknad.

The number of deaths recorded fell from 8,658 in 1897 to 5,440 in 1898, and still further to 4,845 in 1899, and the death-rate from 50·03 to 31·44 and 28·0 in the three last years respectively ; the rate for 1899 being 4·36 per 1,000 below the previous five years' average. The district death-rates varied from 34·05 per 1,000 in Nanjarajpatna to 20·97 in Kiggatnad, but details are not given which would permit of a discussion of the figures. The average rate in rural circles was 27·24 against 35·65 in the towns. The latter are all very small, and the death-rates in some are largely raised by the inclusion in their statistics of the deaths of immigrant coolies ; of the 218 deaths recorded in Mercara town, 69 occurred in hospital, of which 48 were known to have been among coolies from Mysore ; again in Virajandrapet town, of 220 deaths registered, 127 occurred in hospital, of which no less than 121 were known to have been coolies from Malabar.

Among Hindus, who form the vast majority of the population, the death-rate was 27·54 ; among Muhammadans it was 29·61 ; and among the small number included in "other classes," it was 51·06.

The monthly death-rates were highest in July, June, August and September, and lowest in November and April and February, yielding a fairly average incidence.

The death-rate among infants was 251·42 per 1,000 for males and 223·18 for females ; the infantile mortality figure calculated on the births being 231·3 against 265·4 in the previous year. Among boys and girls of between one and five years of age the rates were 24·40 and 19·30 per 1,000 respectively, showing a considerable decline during the last three years. In the two age periods 10–15 and 20–30 the female death-rates were the higher, and the rates for both sexes were exceptionally high in the periods from 20–50 inclusive, doubtless owing to the mortality among adult immigrants. The average death-rate for males was 28·52 per 1,000 and for females, 27·35.

Bombay.—The number of births registered in the Presidency of Bombay, including Sind, was 685,348 against 582,371 in 1898 ; the rate per 1,000 on the census population is 36·42, compared with only 30·94 in the previous year and a quinquennial average of 34·41. This increase was noted in all the registration districts, but in the collectorates of Broach, Panch Mahals, Thar and Parkar and the City of Bombay there was a falling off as compared with the rates for 1898. The highest district rates were registered in Khandesh, 52·85 per 1,000, Nasik, 49·44, and Ahmednagar, 45·76 ; and the lowest in

Hyderabad and Thar and Parkar, both with rates of 21·51 per 1,000, and Bombay City, 12·88. The Hyderabad and Bombay rates vary little from the average, they are always the lowest, and as regards Thar and Parkar, it is explained that famine and consequent emigration account for a decrease of nearly 7 per 1,000 in the birth-rate as compared with that of 1898. In rural areas the average birth-rate was 37·80 per 1,000, showing a rise of 5·9 per 1,000 over the figure of the previous year; in towns it was only 26·48, but this also was 2·4 per 1,000 higher than in 1898. The urban rates were again much affected in several places by the exodus on account of plague; for instance, the lowest rates are recorded for Poona, 8·10 per 1,000; for Belgaum, 11·85; and Bombay, 12·88; and these were all affected by plague. The highest rates are returned from Vengurla 73·32; Borsad, also highest in 1898, 64·97; and Nandurbar 63·23; 21 out of the total of 56 towns record a birth-rate above 40 per 1,000.

The percentage of male to female births was 108·01, slightly lower than that of recent years, and it varied from 133·25 in Hyderabad (and this is a feature of the figures from Sind as a whole) to 102·75 in Dharwar.

The total number of deaths registered was 672,269, or 123,444 more than in the previous year, and the death-rate on the census population rose from 29·16 in 1898 to 35·72 in 1899, as compared with the quinquennial average of 32·31. Nearly two-thirds of the increase, as compared with the previous year, is attributed to an enormous rise in the death-rate from "other causes," from which there were 78,537 more deaths than in 1898; no less than 29,826 deaths under this heading are recorded in Bombay City alone, giving a death-rate of 37 per 1,000. The increase has been very marked from 1897 onwards, and since 1896 the deaths thus registered have increased to the extent of over 250 per cent. The Sanitary Commissioner attributes this striking feature of the returns to improved registration, and certainly the number of deaths returned under the inclusive term "fevers" has fallen off during the last two years to an extent approximately equal to the rise in the number under "other causes." To plague 96,596 death are attributed against 86,191 in the previous year, a ratio per 1,000 of 5·13 as compared with 4·58 in 1898. The highest district death-rates were 69·54, 49·67 and 49·62 in the City of Bombay, Poona and Nasik respectively, where plague was prevalent; the lowest rates were 17·48, 16·97 and 13·87 in Shikarpur, Upper Sind Frontier and Hyderabad, all in Sind, where registration is defective.

In rural areas the average death-rate was 31·76 per 1,000 against 64·10 in the towns, both showing a considerable rise over the figures of 1898. Among the latter the highest rates were returned by Umarkot, 228·77, Nasik, 153·77, and Poona, 128·02. In the first case the enormous mortality is ascribed to fever affecting a population whose natural resistance was impaired by privation; in the two latter cases plague was the chief cause.

Christians and Hindus died at the rates of 38·66 and 38·12 per 1,000 respectively; the death-rate for Parsis being 32·06, and that for Muhammadans 25·98; while "other classes" exhibited, as usual, the lowest mortality, viz., 12·74 per 1,000.

As regards the seasonal incidence of mortality, it was decidedly higher in the first four and last five months of the year than in in May, June and July, when, as usual, it was at its lowest.

Male infants died at the rate of 212·15 per 1,000 and females at the rate of 181·80, as calculated on the obsolete census population, the corresponding provincial infantile mortality rates per 1,000 of births are 202·71 and 187·86 respectively, and in the City of Bombay we find the enormous rate of 798·69 recorded, a plain indication of a most lamentable condition of the public health. Children between the ages of 1 and 5 years had death-rates of 49·15 per 1,000 for boys and 46·80 for girls. The mortality among females was higher than that of males in the 5 to 20 age periods inclusive, the average rates at all ages being 36·48 for males and 34·90 for females.

Burma.—As explained in this report for 1898, a slight reduction was made in the population referred to in the registration returns of Lower Burma, by the exclusion of certain inaccessible tracts which are patrolled only at somewhat irregular intervals. This re-arrangement has been carried still further, and in consequence the total population figure which stood at 4,510,697 has been reduced for vital statistical purposes to 4,461,027. The aggregate population of these excluded tracts amounts to 64,599, and during the year 1899 the birth and death rates recorded among them were 35·99 and 24·78 per 1,000 respectively, figures which exhibit a great advance on those of the previous year, but as the area and population have been largely increased no fair comparison is possible. In Lower Burma the total number of births recorded in 1899 was 165,229, a ratio of 37·04 per 1,000 as compared with 153,838 and 34·11 per 1,000 respectively in the

previous year, which had also shown a similar increase over the record for 1897; the excess over the decennial average rate amounts to fully 10 per 1,000, and we have here another instance of the highest birth-rate on record, a result to which the attention recently given to registration has largely contributed. Still, much remains to be done as is evident when the variation in the rates is taken into account. We find among the districts, Pegu with 46·08 per 1,000, Myaungmya with 44·81 and Henzanda with 43·99, while Rangoon returns 17·55 per 1,000, Hanthawaddy 31·36 and Akyab 32·18. This disparity is even more marked in the towns, and after excluding Rangoon (17·55) and Akyab (16·40), where the great disproportion of the sexes may be held to be largely accountable for their low rates, we find the figures ranged from 56·83 in Kawkareik and 45·73 in Myanaung to 16·90 in Yandaon and 21·14 in Kyaukpyu, yielding an average of 26·09, or fully 12·58 per 1,000 below the average recorded in rural circles.

The percentage of male to female births was 108, ranging from 114 in Toungoo to 101 in Thayetmyo.

The number of deaths registered was 121,771 and the death-rate was 27·30 per 1,000 as compared with 26·13 in 1898 and 24·40 the mean of the previous five years. The Irrawaddy division which returned the highest birth-rate yielded also the highest death-rate (29·12), and similarly the lowest death-rate (22·57) was recorded in the Minbu division, in which the birth-rate was lowest. The district rates varied between 44·03 in Rangoon and 32·57 in Pegu to 20·55 in Akyab and 22·47 in Prome; the average for rural circles being 26·23 against 34·46 in the towns, among which the highest rates were 59·09 in Kawkereik and 53·60 in Myaungmya, and the lowest 15·44 in Paungde and 18·96 in Sandoway. Where the rates were highest cholera and small-pox were unusually prevalent; 4,942 deaths were recorded from the former disease in Lower Burma during the year, only one district being free from the disease, but the fact that the case mortality is returned at 95·31 per cent. makes it clear that probably nearly half the cases were unrecorded. Under such circumstances the difficulties attending the task of marking down the factors of causation and of importation of the disease are rendered well nigh insuperable.

Among the different sects, the highest death-rate was registered among Hindus, 37·50, due chiefly to the excessive mortality among the immigrant population of Rangoon, where the rate reached the high figure of 54·84, and although these outlanders live under far more insanitary conditions than the indigenous Buddhists, it is propable that the census population figure is far from accurate. For "other classes," who number some 94,000 souls, the rate was 31·11 per 1,000, but here again the census figure is doubtless defective. The Buddhists forming the bulk of the people had a death-rate of 27·94, followed by the Muhammadans with 22·09 and the Christians with 17·45 per 1,000.

The highest numbers of deaths were recorded in July, August and June, and the lowest in January, February and March, an incidence which may be taken as fairly normal.

Among male infants the death-rate was 294·49 per thousand living, as compared with 212·77 among females. The true infantile mortality rate for both sexes works out at 185 per 1,000, ranging from 357 in Rangoon to 102 in Tavoy. The average for the whole Tenasserim division is only 145 against 204 for the Pegu division, and these facts have an important bearing on the completeness of registration in the respective areas.

Boys and girls between one and five years of age died, respectively, at the rates of 38·93 and 32·44 per 1,000. At all age periods, save 30–40 when the female rate slightly exceeded that of the male, the male death-rates were the higher, the average being 29·04 per 1,000 among males and 25·34 among females.

In Upper Burma registration in 1899 was extended to 13 towns as compared with nine only in the previous year, and for the first time vital statistical records were instituted in the rural areas. For the present, the returns are kept separate from those of Lower Burma, but following on the census of 1901, it is intended to consolidate the whole of the statistics for the combined province.

The total population (census of 1891) on which the death-rates are based is 2,454,288, of which the vast majority, 97 per cent., are Burmese, but, for the present, birth registration is confined to the 13 towns, with an aggregate population of 311,605. It is clear that in a progressive area open to immigration an enumeration carried out nine years ago must be a defective basis for calculation; moreover, the first attempts at registration will naturally possess an approximate value only. But after making all allowances, the figures must be considered extremely good and encouraging.

The total number of births recorded in the towns was 10,484, or 33·65 per 1,000, as compared with 37·04 for Lower Burma as a whole, or more reasonably with 26·09, the

urban rate in the contiguous area. Pyinmana recorded a rate of 41·78 per 1,000, and Yamethin of 41·46, while Minbu returned only 4·81, and Pagan 10·54, rates due undoubtedly to faulty registration which time and use will improve. The percentage of male to female births ranged from 123 to 88.

The deaths were recorded for the total population, urban and rural, and numbered 51,615, giving a ratio per 1,000 of 21·03. The districts recording the highest rates were Kyaukse, 32·83, and Mandalay, 31·86, per 1,000, as compared with the lowest rates in Magwe, 12·91, and Myingyan, 14·13. The death-rate in rural areas was 18·98 as against 35·15 in the towns, among which the highest rates were 54·62 in Monywa and 42·55 in Pyinmana, and the lowest were 19·26 in Minbu and 21·39 in Kyaukse. But the average urban death-rate in Upper Burma, 35·15 per 1,000, is notable chiefly as exceeding that of Lower Burma, 34·46 per 1,000 ; there were fewer deaths from small-pox, dysentery, and diarrhœa and injuries, but many more from "other causes," in the former as compared with the latter.

The figures have a special interest as demonstrating the characters that may be looked for in vital statistics in areas where registration is undoubtedly and admitted defective, and so, of affording indications for test and comparison with the returns received from areas from which a far higher standard may reasonably be expected.

History of Chief Diseases.

Cholera.

It is the custom to epitomize in this place any facts bearing on the etiology of cholera which observation and research have brought to light during the past twelve months. Once more it must be admitted that there is no epoch-marking advance to chronicle; at the same time everything is of importance that serves to elucidate, in however small degree, any single point in a fascinating epidemiological problem.

"*Comma*" *Organisms in Drinking-water.*—Some observations made by M. Haffkine, Director-in-Chief of the Plague Research Laboratory, Parel, Bombay, in collaboration with Captain Lamb, I.M.S., have an interesting bearing on the question of the relation of infected water-supplies to cholera outbreaks. Advantage was taken of the prevalence of cholera in the famine areas of Gujarat during the months of April and May, 1900, to make a bacteriological study of a series of 33 drinking-water samples taken in 14 localities where the disease was either actually present or had only recently subsided. When collecting the specimens, Captain Lamb noted carefully all particulars as to the locality and source, and the conditions as to the prevalence of cholera ; at the same time he prepared microscopic specimens and cultures, which he merely numbered and sent to the Laboratory at Bombay for examination ; this latter part of the work was thus done independently of the officer who had a knowledge of the origin of the specimens.

Of the 33 samples examined, "curved bacteria, belonging to the class of comma-shaped bacilli," occurred in the microscopic specimens obtained from ten ; in four of these ten the baccilli were isolated in pure culture and submitted to further study. One of these latter answered in every respect to all the typical tests of the cholera "comma bacillus." A second corresponded thereto in many essential points, but differed in two important characters ; while the remaining two, though morphologically classed as "commas," differed markedly from typical cholera microbes.

Notwithstanding the above variation, the following correspondence between the presence or absence of comma-shaped organisms and the prevalence or otherwise of cholera was found. Comma curved baccilli were found in the samples taken from eight of the 14 localities ; they were absent from the remaining six. In seven of the eight localities cases of cholera were still occurring either daily or at brief intervals, and in one place only there had been no cases for 39 days before the samples were taken, but it was subsequently reported on good authority that a recrudescence of the disease had occurred here "shortly after." On the other hand, in five of the six places in the water from which no "commas" were detected in the Laboratory, Captain Lamb's notes show that there was no cholera ; while in the sixth place "sporadic cases" were noted. In all, 278 specimens were examined in arriving at this independent confirmation of the information obtained locally, and the correspondence, whatever its real value, is worthy of note, all the more so as it confirms a similar result arrived at in the exhaustive survey of the water-supplies of

211 localities in Calcutta undertaken by M. Haffkine in the cholera season of 1894. Specimens from 110 "tanks" were then examined, and of these—

(*a*) 46 were tanks round which cholera existed at the time ;
(*b*) 5 were tanks round which cholera had existed from four to six weeks previously, but had since disappeared ;
(*c*) 59 were tanks round which the disease had not appeared at all during the four months of that year.

Out of 46 in category (*a*) comma-shaped bacilli were found in 42, *i.e.*, 91·3 per cent., out of the five in (*b*) these organisms were found in none, and of the 59 in (*c*) "commas" were found in 11 only, *i.e.*, in 18·8 per cent., and were not found in 44, or 81·4 per cent.

The vibrios found in the Gujarat and Calcutta waters varied greatly in their detailed characters, and it is probable that only a small proportion of the whole were true cholera "commas" ; but it is suggested that the prevalence of this morphological type in places where cholera exists, and their relative absence from places free from the disease, can be best interpreted by the supposition that the whole class, including the typical cholera "commas," require for their existence similar or very comparable conditions ; on the one hand, when these conditions are inimical to the cholera bacilli, no vibrios of any kind are to be met with ; and on the other hand, when conditions favour the growth of curved bacilli in general, the typical cholera organism develops and propagates in large numbers, and possibly causes an outbreak of the disease.

It would have added to the interest of these observations if the different vibrios isolated had been tested by Pfeiffer's reaction. Mr. Hankin, who has devoted much study to the subject of the micro-organic flora of water-supplies in connection with cholera outbreaks, has made some experiments on this point. Starting with the assumption that the microbes isolated from patients suffering from the disease will give the agglutination reaction with the serum of an immunised animal, it does not follow that cholera-vibrios found as saprophytes in the endemic area should similarly react to the specific test. Such vibrios may have existed for an indefinite number of generations in water or mud, and have never been in contact with the tissues of a susceptible animal. In an outbreak at Bombay he therefore took the opportunity of putting this question to the test. He isolated over twenty vibrios from the pipe-water, and about twenty more from the well-water and mud in an area where cholera was prevalent, and he found that the vibrios from water, with one exception, did not react with Pfeiffer's test ; the vibrios from mud reacted clearly but slowly, whereas those from patients' dejecta reacted instantly and strongly so as to produce a dense clot from the emulsion. These experiments were repeated subsequently in an outbreak near Agra, the microbes being isolated from a well, the supposed source of the epidemic, in which a woman suffering from "diarrhœa" had committed suicide. A large proportion of the vibrios gave a most marked reaction with Pfeiffer's test, but subsequent to successive cultivations on Agar-Agar, the test serum lost all agglutinating power upon them. Hence this supposed distinctive character of the vibrio, originally present to a marked degree, was lost after a few days' existence on Agar-Agar, but at the same time the original microbes, not submitted to Agar, still gave the reaction. It would be outside the scope of this report to suggest the consideration to which these facts give rise ; they are sufficiently obvious as bearing on the established facts of variation with the environment, which, when taken into account with the variation of the natural intrinsic predisposition of the human organism, afford the key to many of the epidemiological problems presented by the disease.

M. Haffkine's note concludes with a brief synopsis of the results of the bacterioscopic examination of the water from wells, situated in the same area, and which had been treated with permanganate of potassium. Of 25 wells of which it is reported that they had been treated with the salt, some more and others less frequently, but all within a few days of the date the samples were taken, eight were found to contain "commas" ; one of these latter, a well treated every second day, had true "cholera bacilli." The remaining 17 wells were free from "commas," and in one well that had not been treated, "commas" were found in large numbers. He is careful to add that "these data alone . . . do not permit of any definite conclusion as to the efficacy or otherwise of the permanganate process of treating infected waters."

Every exact observation of the kind has a definite value, however far from conclusive ; theories must be tested by an appeal to facts on each definite issue ; at the same time the careful study of the broad epidemiological facts of outbreaks must be sedulously pursued with less of an agnostic tendency to label them capricious and baffling. An instructive note by the Sanitary Commissioner of Madras offers a good example of the

promising methods of observation that might be profitably pursued more generally. In connexion with the question as to why, when cholera prevailed in every district in his province, only 10 per cent. of the total number of villages was attacked, it being suggested that "there is propably little distinguishable difference between those that suffered and those that escaped," he demurs to the implied premiss that the causative agent is capable of being present in equal potency and under equally favouring circumstances over the large area of the presidency with its different geographical and climatological features. The important factors of human inter-communication, of lines of traffic, of the habits of the people as regards their water-supplies, and the nature of these supplies, all go to make up "sanitary conditions" which vary vastly in their incidence and in their resultant effects in different areas. As regards the water-supply factor, it is obvious that a community that depends on one open surface "tank" must be altogether in a different position towards a water-borne disease than one which possesses a large number of deep wells. And further he gives striking illustrations of the distinctly characteristic incidence of the disease in its epidemic form, in an area watered by a river and dotted with villages at greater or less proximity to its banks. One is struck by the fact that whilst the villages along the banks are almost invariably affected, those more distant on either side escape in a fairly direct ratio with the distance, provided their water-supplies are self-contained and not drawn from the stream; at the same time, a distinct relation is to be traced between disease incidence and local lines of communication. In one instance "for every ten villages within five miles of either bank of the river, 1·34 were affected against 0·24 in every 10 beyond that distance." Moreover, if the affected villages be picked out in colour on a map, "a curious fan-like aspect of attacked localities is exhibited, a result that would seem to imply a contamination of the main stream and the distribution of the virus by the irrigation channels as one approaches the coast." Further observations in support of this view are given in the provincial records in this section, where also attention is directed to the characteristic and very definite contrast in the seasonal incidence of the disease from year to year in the two main geographical and climatological areas into which the Madras Presidency is naturally divided. Much confusion and apparent caprice in the incidence of the disease in time and place has arisen from a consideration of the returns from whole provincial areas, but if the natural integral areas be studied separately, in the light of a knowledge of local conditions, each is found to present a definite and characteristic epidemiological picture. It would overburden this report, which is restricted to a brief resumé of the history of cholera during the past year, to adduce examples in support of the contention that in the sense of an ordered sequence of events a "law" may reasonably be adumbrated, if we may not define or explain its action, for the disease prevails under certain definite conditions peculiar in the sum to each locality, though doubtless in a measure common to all. It is merely to emphasize the necessity of research and observation on the opposite but contributory lines indicated that these few remarks are made.

Anti-cholera Inoculations.—The experiments in cholera prophylaxis were continued at the Purulia and Salkea coolie-depôts in Bengal, the total number of inoculations performed during the year being 2,388, the figures for the two preceding years having been 4,296 and 10,950 respectively. The falling off is attributed to the fact that cholera being less prevalent in the coolie track, the urgent inducement was wanting, and some agents preferred not to incur the small pecuniary loss the operation involves, though it is said that all agents are convinced of its value, and that a few insist upon its performance. That the downward tendency exhibited by the figures given above is merely temporary is well shown by the fact that during the first four months of 1900, no less than 8,423 inoculations had been performed. As regards the results, the Labour Immigration Report (Assam, 1899) shows that while the death-rate on the uninoculated during transit to the gardens was 0·294, there was no death among the 2,246 inoculated coolies. Returns were received from only four gardens having aggregate totals of 1,161 uninoculated and 346 inoculated on the staff; there were 36 cases of cholera among the former and 17 among the latter, while the deaths among the two classes were 12 and 10 respectively; this gives a case percentage of 3·1 among the uninoculated, against 4·9 among the inoculated, while the case mortality was 33·3 per cent. among the former and 58·8 per cent. among the latter. It is to be noted, however, that eight of the ten deaths among the inoculated occurred over two years subsequent to the operation, and in any case the figures are too meagre to justify definite conclusions.

Dr. Powell, in a report on all the cases of cholera that have occurred on the estates and in the villages in his practice since the commencement of the prophylaxis experiment, sums up the results as follows:—"There have been 198 cases with 124 deaths among

6,549 persons not inoculated, compared with 27 cases and 14 deaths among 5,778 inoculated individuals. Had the incidence been the same in both classes, the inoculated would have had 174 instead of 27 cases, and 109 deaths instead of 14; the mortality therefore among the non-inoculated was nearly eight times greater than among those inoculated."

I may mention that in view of the prevalence of famine during the early months of the current year, I put forward a proposal that a skilled officer should be deputed to visit the famine camps for the purpose of giving to all willing to receive it the benefit of M. Haffkine's process, as the circumstances appeared to offer an excellent opportunity of obtaining valuable evidence of its practical utility, the harmlessness of the operation, at least, having been definitely established. It was to be clearly understood that no compulsion should be attempted. The Government of India were, however, of opinion that the people, forced by privation to the camps, would not appreciate the entire freedom of choice, which it is of course essential to preserve in this matter, and the great force in the objections raised to the proposal outweighed in my opinion the probable benefits that might have accrued. As it has unhappily proved, cholera has in certain areas added greatly to the horrors of famine, and increased the difficulties of the successful working of the relief camps.

The Distribution of Cholera in India, 1899.—In last year's report the cholera mortality in 1898 was shown to be the smallest on record for 18 years. The number of deaths fell to 152,703, giving an average ratio per 1,000 for the whole country under registration of ·70 only. Again in 1899 the disease was far less prevalent than usual; there were altogether 171,410 deaths returned, a figure which is considerably less than that recorded in an average year in Bengal alone, and the ratio on the census population did not amount to more than ·78 per 1,000, as compared with a quinquennial mean of 1·84. Of the total mortality, Bengal alone accounted for fully 62 per cent., but even here the death-rate from this cause was only two-thirds of the average of the past five years; and it is only in the Punjab, where 1,816 deaths were recorded, that we find the quinquennial mean slightly exceeded. Central India, Hyderabad State and Coorg were entirely free from the disease in a fatal form; Ajmer-Merwara returned only one death and the Central Provinces only 76 deaths.

The statement annexed shows the total numbers of deaths attributed to cholera in every province in India in each year from 1877 onwards:—

Statement showing the deaths from Cholera in the different Provinces in India from 1877 to 1899.

YEAR.	Bengal.*	Assam.	N.-W. P. and Oudh.	Punjab.	Central Provinces.	Berar.	Rajputana.	Central India.	Bombay.	Hyderabad.	Madras.	Mysore.	Coorg.	Lower Burma.	Ajmer-Merwara.
1877	155,305	11,307	31,770	29	3,418	842	60	926	57,228	7,414	357,430	2,902	†	7,276	11

* Excluding Calcutta from 1877 to 1892.
† Statistics not available.
‡ Including 30 deaths in Cantonments.
§ Excluding Zamindaries.

The next table exhibits the seasonal incidence of the disease, and the most notable feature in this respect is the exceptional mortality falling in the last quarter of the year. But, as already explained, the figures for each provincial area must be studied separately, and further than this, a reference to the local sanitary reports, in order to distinguish the true geographical and climatological groups, will alone afford a true picture of the characteristic incidence of the disease in time and place.

Statement showing the Deaths from Cholera registered in the different Provinces by Months during the year 1899.

PROVINCE.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	TOTAL.	RATIO OF DEATHS PER 1,000 OF POPULATION. 1899.	1898.

* Excluding Zamindaries.

Cholera in Bengal.—In Bengal in 1899 the number of deaths registered as due to cholera was 107,678, or 1·58 per 1,000 of the population, against 65,020, or a ratio of 0·91 per 1,000 in the previous year, the average for the previous 10 years being 2·59. No district was entirely exempt from the disease in the year under review; it was reported from 17,217 villages, or 7·67 per cent. of the whole number, against 11,307 in 1898, and it prevailed epidemically in 42 registration circles, 90 circles being exempt, as against 130 in 1898.

The highest district death-rates were 6·28 per 1,000 in Malda, 4·59 in Puri, 4·45 in Bogra, and 3·29 in Cuttack, the mortality being greater in 31 districts, and somewhat less in 14, than it was in 1898, a year of exceptional low prevalence.

In Malda the disease existed in a sporadic form during the first eight months of the year, but suddenly assumed epidemic proportions in September, and so continued to prevail throughout the rest of the year, the maximum being reached in November, when 2,742 deaths were recorded. The thanas most affected were those situated on the Ganges and between this river and the Mahanandi, and it is recorded that following on the terrible cyclone that blew over Bhagalpur in October, dead bodies were discovered floating down the Ganges to be subsequently stranded in the *churs* all along the western border of the district. The epidemic also spread inland from the eastern bank of the river, but stopped short of the banks of the Mahanandi.

The high death-rate in Puri was chiefly due to a severe outbreak among the large body of pilgrims congregated there during the last Rath Jatra festival in July. Most of these pilgrims came from Calcutta, the trains bringing large numbers daily to Bhadrak which the steamers from there were unable to cope with, the result being an accumulation of exhausted travellers upon the return roads, and especially in Bhadrak itself, "where there was no provision of food and shelter, and where the water is probably highly polluted." A very large proportion of the devotees were widows who left their homes surreptitiously without adequate provisions, and no factor favourable to an outbreak of the disease was wanting: starvation, bad indigestible food, such as travellers perforce must depend on, polluted water, overcrowding, and all the consequences of no proper accommodation for the undeniable calls of nature. A special report on the subject has been submitted and is under consideration by the Local Government. In Bogra and many other districts the special intensity of the local epidemics was attributed to "the early cessation of the rains and the consequent pollution of the water-supply," the Sanitary Commissioner being of opinion that the usual scouring and cleansing effect of heavy rainfall on open water sources was wanting.

In the rural areas the average death-rate was 1·48 per 1,000 as compared with 2·17 in the towns; of a total of 152 of the latter, the record of 23 is entirely free from a fatal case, and 20 other towns returned only one or two fatalities. Puri town with 960 deaths has a mortality ratio from this one cause of 33·34 per 1,030, but, as previously explained, the deaths occurred chiefly amongst pilgrims; the mortality was also exceptionally high in Muktagachha, 9·14 per 1,000, in Muzaffarpur, 9·08, in Colgang, 7·7, and in Darbhanga, 6·53.

The seasonal incidence of the disease presents the unusual feature of an excessive prevalence during the months of October to December in Bengal Proper and Bihar, whereas it is commonly associated with the hotter and drier months of April and May. Orissa suffered most in July, August, October and September, with a minimum in January, March and February. It is noticeable that while the disease was at its worst in Orissa during the height of the rains it was at its lowest ebb, as usual, in Bengal Proper. Chota Nagpur, as is so frequently the case, was almost free throughout the year, the mortality never being in excess of ·03 per 1,000 in any one month, and this highest point was reached in June.

There were nine admissions to hospital for cholera from among the European seamen of the port of Calcutta during 1899, all of which proved fatal, equal to death-rate calculated on the average strength of 7·50 per 1,000 against 1·62 in 1898. Among the native floating population of the port there were 36 deaths in 1899 against 49 in the previous year, giving ratios per 1,000 of 1·40 and 1·91 respectively on the estimated population.

Assam.—The number of deaths attributed to cholera in Assam was 8,380, equal to a death-rate of 1·66 per 1,000, as compared with 2·22 in 1898 and 3·75 the average for the previous five years; indeed not since 1887, when the number of deaths was 7,941 (1·75), do we find a mortality figure so low as the one now recorded. The actual incidence in the different geographical areas, that is to say, in the two great valleys, did not vary

materially, and the chief feature of the seasonal incidence was the rise in the number of deaths reported in October and the culmination in November and December, in which two months fully half the total deaths occurred. The mortality during the rest of the year was, as regards the Surma Valley, most marked in the first four months, and in the Brahmaputra Valley in the April–July period, a relative seasonal incidence that has been frequently noted in previous years.

The only district in which a notable increase occurred as compared with the previous year was Goalpara, which reported 2,284 deaths, or a ratio per 1,000 of 5·05, against 1·86 in 1898. Kamrup comes next with 2·08 per 1,000, and is followed by Darrang and the Garo Hills, each with 1·70; the lowest rates were 0·56 per 1,000 in the Naga Hills district, and 0·39 in the Khasi and Jaintia Hills, accounted for by one and 19 deaths respectively; elsewhere the rates ranged between 0·64 and 1·37 per 1,000.

As regards Goalpara, it is noted that an outbreak in the *sadr* town and district of Dhubri, lasting from October to December, occasioned just one-half of the total number of deaths registered; "it apparently originated in the river-side depôts amongst batches of tea-garden coolies from whom it spread." However introduced, if introduced, and there is a discrepancy in testimony borne on the subject by the Sanitary Commissioner and the Local Government, the disease claimed only 21 victims among the 24,449 immigrant coolies during their passage up the Brahmaputra, and only 51 more deaths occurred among them while at the depôts; figures which are even lower than those of 1898, and insignificant in comparison with previous years, and which afford satisfactory evidence of the results of the greater care now exercised in all matters affecting the physical welfare of the immigrants throughout their journey.

The population of the tea gardens is given as 636,208 in the Labour Immigration report for the year, and 999 deaths from cholera were recorded among this number, giving a mortality rate of 1·57 per 1,000, a figure which compares most favourably with that of any recent year, and which, indeed, is scarcely higher than that for the free population living in the same areas, viz., 1·33 per 1,000.

In the province generally the average death-rate in rural areas was 1·66 per 1,000, against 1·71 in the towns. Among the latter there were eight out of a total of 23, in which no death occurred, and in four others there was only one fatality recorded in each. The only considerable mortality was in Tezpur, Gauhati and Dhubri, which, with 50, 45, and 31 deaths respectively, furnished death-rates of 12·47, 5·43 and 6·42 per 1,000 in each case.

North-Western Provinces and Oudh.—There were altogether 8,142 deaths attributed to cholera in these provinces during 1899, a ratio per 1,000 of 0·17, as compared with 0·05 in the previous year, and 1·47 the mean of the antecedent quinquennium; excluding the phenomenal record of 1898, the rate for the year under review is by far the lowest hitherto returned. Four of the 48 districts appear to have escaped altogether, and in no less than 11 others less than 10 deaths are recorded in each. Only 0·98 per cent. of the total number of villages over this large area were attacked, and these yielded 7,563 deaths, a rural mortality rate of 0·17 per 1,000; while of the 99 towns, 62 recorded no fatal case, the remaining 37 returning 579 deaths, and giving a rate per 1,000 on the population of the whole of 0·18.

Among the larger towns, Ghazipur had the highest rate from this cause, viz., 1·67 (75 deaths), followed by Fyzabad-Ajudhia with 1·35 (98 deaths); of the smaller towns, Chunar comes first with 4·55 per 1,000 (52 deaths), and next to this, Nagina, 2·84 (63 deaths); in only two other towns did the rate reach 1 per 1,000.

The maximum prevalence of the disease occurred as usual in August, with a fairly maintained incidence till November; the minimum, 13 deaths, was recorded in February.

Punjab.—Following on a year of almost total immunity from the disease, there were 1,816 deaths recorded in the Punjab in 1899, a larger number than in any year since 1892, save 1896, the year of the last considerable prevalence, when there were 5,146 deaths. The rate per 1,000 works out at 0·09 for the year under review, as compared with 0·02 in 1898 and 0·06 the mean for the previous five years. Ten of the 31 districts appear to have been entirely free from the disease, and in six others only one or two deaths were recorded in each. The largest numbers were registered in Shahpur and Hissar, with 702 and 308 deaths, and millesimal ratios of 1·42 and 0·40 respectively. Lahore with 167 deaths (0·16), Mooltan with 117 deaths (0·19), and Gujranwala with 103 deaths (0·15) are the only other districts in which the figures are considerable.

Only 19 of the 150 towns reported deaths, the fatalities in nine being confined to one or two cases each; Tanda and Urmar in Hoshiarpur with 28 deaths returned a rate of 2·41 per 1,000, and in the cantonment of Mian Mir 70 deaths were recorded, giving a rate of 4·05 per 1,000.

The only considerable outbreaks were those which occurred in the famine camps in the Hissar and Shahpur districts in December. In the former case it is suggested that the disease was imported by coolies from the North-Western Provinces, but no definite details in support of this view are supplied. Three camps were affected, and altogether 389 cases with 297 deaths were recorded, the high mortality being ascribed to the debilitated condition of the refugees. The disease is believed to have been transported thence to the famine camps in Shahpur, and there is the definite evidence that people arriving by train suffered from diarrhœa and vomiting, but "the disease was only recognised after their arrival in camp." Altogether there were 1,186 seizures and 684 deaths up to the end of the year. The Sanitary Commissioner visited all the famine camps and supervised measures for the suppression of the disease.

As regards the seasonal incidence, only four deaths from cholera were recorded during the first six months of the year; 71 fatal cases in July were followed by 433 deaths in August, and thereafter there was a diminished prevalence till December, when the maximum number of deaths, 906, were recorded.

Central Provinces.—During the year there were only 76 deaths registered from cholera in the Central Provinces, the number having been seven only in 1898; there has been no approach to this immunity in the previous records of the province. The death-rate on the total population works out at 0·01 per 1,000, as compared with 2·79 the mean for the previous five years, over 50,000 deaths having been recorded each year, in 1896 and 1897.

One death occurred in April and one in October in the Nagpur district; and there were 10 fatal cases in November and 64 in December in the Nimar district and the neighbouring Burhanpur subdivision. As regards this, the only considerable outbreak, it is noted that 17 villages out of a total of 761 in the area were affected.

Berar.—In this province, which was entirely free from the disease in 1898, the comparatively small number of 541 deaths were reported as having occurred in 1899. Cholera broke out at the end of August simultaneously in two villages in the Amraoti district, on the 2nd September in a village in Ellichpur, and shortly afterwards in two villages in the Akola district. The first two villages are situated on the banks of the Purna river, whence they draw their water supplies. The origin of the outbreak was not definitely ascertained, but some of the inhabitants had recently returned from a fair. Thence the disease spread by human intercommunication to the other villages affected, and prevailed during each of the last five months of the year. There were altogether 1,216 cases with 541 deaths (44 per cent.), the largest number of fatalities, 294, occurring in October, and falling to 35 in December. Three of the six districts were entirely free of the disease, which was remarkably local in its incidence, the mortality rate calculated on the whole population being only 0·2 per 1,000, as compared with 2·6 the quinquennial mean.

Madras.—Save for the year 1895, we have to go back to 1887 to find a cholera mortality in the Madras Presidency as low as that of the year under review. There were altogether 29,082 deaths from this disease recorded in 1899, a ratio of 0·9 per 1,000 as compared with 2 per 1,000 in 1898, and the same figure for the average of the preceding five years. The greatest number of deaths occurred in Salem district, where there were 5,568 (2·8 per 1,000) in Tanjore, where there were 5,864 (2·6 per 1,000), and in Trichinopoly, where 3,287 were recorded (2·4 per 1,000); only two districts were absolutely free of the disease, although in three others, out of the remaining 20, the numbers of deaths reported did not exceed 20 altogether.

The Sanitary Commissioner gives interesting tables showing the seasonal incidence of the disease in the different areas, which are divided into two groups in accordance with their geographical positions, and the consequent climatological conditions, as mainly influenced by the two annual monsoons. As he has been able to show in previous reports, the incidence of mortality is greatest on the south-west monsoon districts during the progress of the south-west monsoon, that is to say, during the June to September deriod; whereas in the north-east monsoon group the mortality is greatest during the prevalence of the rain current, which specially affects these particular areas, that is to say, during the last quarter of the year. Whatever view be held as to the effective relation

between rainfall and cholera, there can be little doubt that, year after year, a definite relation in time is established in the two contrasted areas in the Madras Presidency, a relation, moreover, which finds supporting evidence in the seasonal prevalence of the disease in other provinces, and which is opposed to the usual sequence of events in Lower Bengal.

The rural death-rate was 0·8 per 1,000, 7·65 per cent. of the total number of villages being attacked; whereas in the towns the average death-rate was 1·5 per 1,000, only 50, however, of the total of 93 being affected, and in 11 towns the number of deaths recorded did not amount to 10 in each. The municipal towns suffered at the same rate as the rest (1·5 per 1,000), the highest mortality occurring in Vaniyambodi (18·7), Gudiyattam (14·2), Tiruppattar (11·3), Hospet and Ambur (10·8) and Salem (9·0).

In connexion with the view "that water contaminated by the specific germ is the chief method of local propagation of the disease," the testimony of the District Medical Officer of Salem, the district chiefly affected, includes one or two suggestive remarks. He says that "the worst outbreaks are invariably in taluks where the population is chiefly dependant on river-water for drinking. It was an impossible task to prevent the use of the infected water, or its constant re-infection. In villages and towns dependant on a well-water-supply, cholera outbreaks have been promptly checked by closing infected wells, and preventing infection of others by appointing caste-watermen and guards."

Coorg.—In this small province not a single death from cholera was recorded during the year under review, a fact which it has been possible to record on no less than seven previous occasions during the last 21 years. There were eight deaths in 1898, 106 in 1897 and 49 in 1896.

Bombay.—During 1899 cholera is reported to have caused 8,579 deaths throughout the Presidency, or 4,211 more than in the previous year, the millesimal ratio being 0·46 against a quinquennial mean of 1·48 More than half the total, *viz.*, 4,474, occurred in the district of Belgaum, where the death ratio was 4·42 per 1,000; Karachi district returned 2,394 deaths (4·27 per 1,000), and Dharwar, with 1,335 deaths, had a ratio of 1·27 per 1,000. The disease in its epidemic form was practically confined to these three collectorates; 12 of the 24 districts were entirely free from a fatal case, and it is only necessary to note further that there were 111 deaths recorded in the city of Bombay.

Out of a total of 220 rural circles 26 were affected, but in only nine did the death-rate from this cause exceed 3 per 1,000; the disease was most prevalent in one rural circle each of the Karachi and Kanara districts, in five circles of the Belgaum, and in two of the Dharwar district.

Only five of the 56 towns were affected in any notable degree, although 12 in all reported fatal cases; Karachi, with 2,064 deaths, suffered severely, the death-rate from this one cause being 21·25 per 1,000. Next comes the small town of Gokak in the Belgaum district, which, with 129 deaths, had a death-rate of 10·66 per 1,000.

There are altogether 25,143 villages in the Presidency, but only 461 were affected, and considerably more than half of these were in the Belgaum district, where every fourth village was attacked. The average rural death-rate was 0·37 against 1·09 in the towns.

The disease was most prevalent in April and May, and least in January and December.

Burma.—There were altogether 4,942 deaths from cholera registered in Lower Burma during 1899, a ratio per 1,000 on the census of population of 1·11, as against 0·66 per 1,000 in 1898, and an average of 1·2 for the previous five years. The disease prevailed in every district save one (Toungoo), the highest mortality being registered in Mergui (5·04 per 1,000), followed by Amherst and Myaugmya, with 2·47 and 2·08 per 1,000 respectively.

The percentage of villages attacked was 6·52 for the whole province, but ranged from 16 in the Irrawaddy division to two in Minbu, the average number of deaths recorded on each village being three in the former case and seven in the latter.

The rural death-rate was 1·01 per 1,000 of population against 1·79 for the towns, the mortality in Mergui (17·95), Ngathamggyaung (7·49), and Moulmein (6·67) chiefly accounting for the excess in the category. Out of a total of 33 town-circles, 25 were infected, and 15 returned a death-rate above the average for the province, but the most marked instances have been referred to.

It is noted by the Sanitary Commissioner that the 4,942 deaths recorded represent a mortality of 95·31 per cent. on the total number of cases reported, *viz.*, 5,185; this fact was alluded to in the previous section not only as indicating defective registration, but as emphasizing the difficulties attending enquiries into the etiology of the disease, in its epidemiological aspect.

In Upper Burma the number of cholera deaths registered in the 12 selected districts in 1899 was 2,050, or 0·84 per 1,000 of the population, against 1·11 for the lower province. Only two of the districts were free from the disease in its fatal form, but only 4·7 per cent. of the total number of villages were attacked; the highest mortality was recorded in the Mandalay district with 1·58 per 1,000 (568 deaths), followed by Saigang with 1·45 per 1,000 (356 deaths).

The rural death-rate was 0·79 per 1,000, compared with an average of 1·17 in the towns, eight out of the 13 among the latter being affected, by far the highest mortality being recorded in Monywa, where 133 deaths furnished a death-rate of 21·06 per 1,000.

In both Upper and Lower Burma the season of maximum prevalence was the period from April to October inclusive, but while the disease was epidemic in each month throughout the year in the latter area, no deaths were reported in Upper Burma in January and February.

Summary of cholera registers.—The European troops and the prison population shared the general immunity from cholera enjoyed by the people. Only one case, and this had a fatal result, was recorded among the former; this phenomenal freedom from the disease has no parallel in the medical annals of the army in India. The single victim, an artilleryman, was a patient in hospital, where he had been under treatment for 20 days for palpitation of the heart; at the time, cholera was prevalent among the native population of the cantonment (Mian Mir), and a follower of the battery was seized with the disease and admitted to hospital in the same enclosure as the European Ward. The soldier in question, who was a patient in the latter ward, was attacked four days later with a fatal result. Twenty-seven inmates of the same hospital were promptly removed to an empty barrack and no other case occurred among the troops, although six more of the followers in the lines were attacked. The virus in this case was abundantly present in the surroundings, but nothing definite was ascertained as to the means of infection of the European victim.

Among the jail population, with an aggregate average strength of 98,275, there were only 84 cases of which 51 ended fatally; and these were distributed among 18 jails, of which eight are in Burma, four in Bengal, two in Assam, two in Madras, and one each in the North-Western Provinces and Central Provinces. But the only considerable outbreaks were in the Gauhati Jail (Assam), which returned 25 cases with 18 deaths, and in Moulmein Jail (Burma), where there were 20 cases and 12 deaths; in twelve jails there were only one or two cases recorded in each, and nine of these twelve had each one fatal case.

As regards Gauhati, cholera had been very prevalent in the district and in the immediate surroundings of the jail for over two weeks, when one day no less than eleven prisoners were attacked, the first of whom and four altogether, had been employed in the jail garden, and none of whom had been less than one month in confinement. The garden is watered by a foul tank, the water of which was also used by two sweepers, subsequently attacked, for cleansing the latrine gumlahs. The prison water-supply is derived from the Brahmaputra river, which is filtered under the auspices of the local municipality and subsequently boiled before use by the prisoners, but it is insufficient for bathing purposes, unfiltered water from the same source being laid on; prisoners are known to drink from this bathing supply, and they were also in the habit of washing their hands and feet in the garden tank. Persons having business relations with the jail also had access to the garden, and it is suggested that they infected this source. Having regard to the habit of natives of washing out their mouths after ablution, the medical officer concludes that all the evidence available points strongly to the tank-water as the mode of infection, as no less than seven men attacked, including four of the first cases, were employed in labour that brought them into intimate association therewith. Three barracks and the hospital, accommodating altogether 65 men and in which 14 cases had occurred, were evacuated, and the occupants moved into extramural camps; no case occurred subsequent to this movement.

In Moulmein town, cholera had been prevalent for over four months and cases had occurred in the bazars in the vicinity of the jail; it is also stated that the disease was definitely associated with the use of the river water on which the town stands and from which it draws its supplies.

The jail derives its water from the rainfall collected and stored in a reservoir on an uncultivated hill after percolation through the sandstone, whence it is conveyed in a covered conduit, and is subsequently boiled before use by the prisoners, and this source of infection is absolved of any influence in the outbreak. The details given, however, are

not sufficiently full and explicit to carry conviction on this point. The prisoner first attacked had been rigorously confined to jail for one year, and the medical officer is at a loss to account for the means of his infection; two of the subsequent cases, however, occurred in the persons of cholera sick attendants. But it is to be noted that out of the fifteen cases that occurred in the jail prior to the movement into camp, fourteen were associated with the two main dormitories and the hospital; the under-trial prisoners and the women who are closely segregated in separate enclosures were entirely free from the disease. The outbreak then presents the features, not of a general epidemic from one common source as from the water supply, but rather suggests a casual infection of the first case, transmitted to the second victim who was an attendant on the first, and thence spreading by association among men living in close contact.

The troops of the Native army were not nearly so fortunate as their European comrades. Fourteen bodies of men located in twelve separate cantonments or camps were attacked; there were altogether 247 cases with 135 fatalities. The severest outbreak was that to which the 42nd Gurkha Rifles were exposed en route from Shillong to Abbottabad, when 58 men succumbed out of 105 attacked, including five deaths and eight cases among followers.

The statement below shows, in all cases where the details are available, the number of buildings occupied by the communities attacked, and the proportion which furnished cases of the disease:—

Communities.	Number of buildings occupied by communities attacked.	Number of buildings which furnished cases.	Percentage of buildings which furnished cases.
European troops*	—	—	—
Native troops	1,386	71	5·12
Prisoners	171	41	23·98

* There was only one case, which occurred in hospital.

No special relation between particular meteorological conditions and the occurrence of cholera was established.

Attendants attacked by the disease.—The total number of cases treated among the troops and their followers and the prison population was 322; the aggregate number of sick attendants was 427, and of these last, eight persons in all were attacked, or about 1·8 per cent. Some of these are stated to have incurred the disease by gross carelessness as regards the simplest precautions, for example, eating with unwashed hands, and drinking from the vessels provided for the sick.

In the reports of previous years ample evidence is given of the value of judicious movement of bodies of men among whom the disease has broken out; the registers of the past year testify emphatically to the great and immediate practical advantages of this established procedure, though it is only one of a series of precautions, the whole direction of which is to eliminate one or other of the chief factors from the chain of causation.

It will be interesting to many to see the actual figures showing the death-rate from cholera during the last 20 years in the three groups just mentioned and in the general population, even though all discussion of their significance be avoided on this occasion. The ratios of mortality attributed to the general population must, however, be understood to be only an approximation to the truth, which defective registration makes it impossible to obtain.

Death-rates from cholera per 1,000 *of population for the past* 20 *years in four quinquennial periods.*

—	1880–84.	1885–89.	1890–94.	1895–99.

General population	1·15	1·55	1·59	1·54

Small-pox.

The mortality ratio of India from small-pox was in 1899 reduced by 17 per cent. from that of the preceding year, and by 43 per cent. from that of the quinquennium 1894–98. The highest numbers of deaths occurred in the months of May, April and March; and the lowest in the months of September, October and November. The reduction of deaths was greatest in January and February, and continued up to the end of August; after which there was an increase, greatest in November and December. The total number of deaths for the year was 53,347 against 62,517. Only in the Punjab, the Central Provinces and Lower Burma, among the larger provinces, was the mortality higher than in 1898; and only in Lower Burma and Madras was it higher than the quinquennial ratio. The greatest reduction from the quinquennial ratio was in Assam, and the greatest increase in Lower Burma.

The following table shows the mortality from small-pox in the different provincial registration areas of India in 1899, month by month:—

Statement showing the deaths from Small-pox registered in the different Provinces by Months during the year 1899.

* Excluding Zamindaris.

The highest rural district ratios in India were those of Dewair in Ajmer-Merwara and Puri in Bengal; and the highest town ratios those of Hassan in Mysore, Kawkareik in Lower Burma, and Peshawar in the Punjab. Dewair rural area and Kawkareik town showed the greatest increases over the ratios of the preceding year. The greatest percentage of rural districts with high mortality was in Madras, and the greatest number of districts without small-pox mortality in Bombay. The greatest percentage of towns with high small-pox mortality was in Mysore, and the greatest number of towns without small-pox mortality in Berar. The proportion of child-mortality in total small-pox mortality was highest in the Punjab, and lowest in Coorg. There were two deaths from small-pox among the European seamen in the port of Calcutta, against none in the three preceding years; but there were none in the native floating population. In the Bombay harbour only one case of small-pox was observed, in the person of a European passenger who arrived by mail steamer.

The following are the more interesting of the remarks made on the subject of small-pox by the Sanitary Commissioners of the various provinces:—

Bengal.—As in the previous year, the three highest ratios were those of Puri, Cuttack and Balasore. In fact, over two-thirds of the total deaths from this cause in the province were returned by Orissa alone. Although the death-rate in Puri is lower than that in 1898, it was still very high,

and was due to the continuation of the outbreak which began last year, the epidemic being chiefly confined to thanas Puri, Pipli and Khurda. As regards the very severe prevalence of the disease in Cuttack, the Civil Surgeon reports as follows :—"The disease was prevalent during March to July in Salepur, Jagatsingpur and Jajpur, where people resort to inoculation. Cases of inoculation from these places were sent up for trial in the magistrate's court, and all the cases were proved against the culprits, who were heavily fined. The cause of the heavy mortality from this disease is the want of protection by vaccination, as the people are intensely ignorant, and do not appreciate the beneficial effect of this prophylactic, but always resort to inoculation."

Assam.—The disease has been very satisfactorily kept under by efficient vaccination in the Surma valley, especially in the Cachar district, in which it was practically non-existent. In the Brahmaputra valley the results were not quite so good ; many large sections of the people entirely refuse vaccination ; and, as it cannot be forced upon them, the only thing we can do is to wait until the mortality rises so high that their fears overcome their prejudices. The Darrang district was the worst.

Central Provinces.—As usual, the disease was most prevalent in the hot months, and declined in the cold season, although December proved an exception to the rule.

Berar.—Small-pox was not so widespread or so intense as in the previous year. There were 305 deaths in 165 villages as against 592 in 251.

Madras.—It must be remembered that vaccination is not compulsory in rural areas, and although a large section of the population appreciates its benefits, there is still some repugnance in submitting to the operation. Even where the mothers have no objection to the operation it is difficult to convince them that infants under one year of age can successfully bear the operation. Hence the risk to infantile life is considerable, more especially as a Hindu mother considers it necessary to show respect to the goddess of small-pox by joining in assemblies in crowded rooms, where, in the presence of the small-pox patient, ceremonies are performed to the deity. Revaccination, which, as the population emerges from being but a partially-protected to being a fairly-protected population, must become of greater importance, is rendered difficult in advance by it being conceived that small-pox is a disease of infancy, from which the adult has little real cause to protect himself—a conviction obviously of the same origin as the European estimate of measles, namely, that infection spares not the child, but passes over the adult, who, it is apt to be forgotten, has usually acquired immunity consequent upon an attack of the disease in infancy. The appearance of small-pox in a locality is at once followed by special vaccinators being deputed to the spot, but, unfortunately, it does not follow, in certain areas, that their services will be utilised by the people, as a distinct prejudice against vaccination being conducted in epidemics is often met with. Disinfection of infected houses and clothing is also employed. Much prejudice was encountered in the preceding year against vaccination, the people having hopelessly confused the operation of inoculation against plague with that against small-pox ; or, put in other words, an opinion existed that plague was being spread amongst the people by inoculation under the guise of vaccination. Happily, what at one time threatened to be a serious cause of retardation of vaccination has now subsided, as a result of common sense prevailing over the hysteria of panic.

Coorg.—In every instance where the disease broke out the first case was an imported one. "It is satisfactory," adds the Commissioner of Coorg, "to note that the public have regained their confidence in vaccination measures, which was seriously shaken by the plague inoculation scare, and freely come forward to be protected. It must be remembered that vaccination is only compulsory in the municipal towns."

Bombay.—The number of deaths from small-pox during the year, though higher than in the preceding year, was the lowest recorded, with two exceptions, during the last 12 years. The figures may be considered very satisfactory, and they testify to the exceedingly good vaccination work which now for some years has been done in the presidency.

Burma.—The importation of small-pox and its dissemination throughout the province are attributed to the unprotected cooly immigrants from India, large numbers of whom come to the country during the harvest season to reap the rice crop, and it is to be noted that small-pox prevalence was greatest in the Pegu division in the areas adjoining Rangoon. Most of the district reports assign the cause of the first cases to importation, and its further spread to the practice of inoculation, which would appear to be general throughout the province, and to be resorted to by the people as a protective measure when epidemic small-pox appears. Though inoculation is undoubtedly an active agent in the diffusion of infection, yet the most potent cause is insufficient protection of the people by vaccination ; for experience elsewhere has conclusively demonstrated the protective influence of efficient vaccination, and how small-pox mortality decreases in direct proportion to the protection of the population by vaccination. In Germany, for instance, where nearly everyone undergoes vaccination and revaccination, there is but little small-pox.

Plague.

There was a great increase of plague mortality in Bengal, the Central Provinces, Bombay, Madras, Mysore and Hyderabad, while it fell off in the North-Western Provinces and Oudh, the Punjab and Rajputana. Imported or suspicious cases were discovered for the first time in Berar, Ajmer-Merwara and Burma, but none in Baluchistan. Neither imported nor indigenous cases were observed in Assam or

Coorg. The following table shows the statistics, so far as they have been received in this office :—

* From 1st January to 30th December, 1898. † Imported cases.

Before the completion of this report for the year 1899, Chapter VI. of the Report of the Indian Plague Commission, dealing with "Measures for the Suppression of Plague," has been received in India ; and in a resolution on it, dated the 16th July, 1900, the Government of India has laid down the rules of the general policy to be adopted throughout the country. It has, therefore, not been considered necessary in the following pages to record details of local procedure systematically, though some may be given incidentally. The resolution imposes not a new but a more fixed policy ; it clears up and settles points that were disputed, establishes well-tried measures, improves others, and rejects such as experience has shown to be inexpedient or impossible.

The following are short notes on a few points of scientific and practical interest concerning plague :—

Insects.—The question as to the participation of insects in the conveyance of plague is far from settled. In Oporto one patient suffering from the pustular form of plague said that his disease began from a bug-bite ; and it was judged that the first man attacked in Sydney had been infected by a flea-bite. It is considered probable by some that the infectivity of old rags resides in the fleas harboured therein ; and it has even been suggested that man is but incidentally affected by the rat-disease, plague, which, but for the mediation of insects, would remain confined to rodents. Daly, of Newchang, has reported a case in which a servant carried out a dead rat in his hands, and was attacked by plague the following day. The shortness of the incubation period suggests the possibility of previous infection. Otherwise, similar cases, reported by Simond and by Hankin, have been noticed in previous reports. Matignon in Mongolia noted, like Yersin, a heavy mortality among flies in plague time. The chief of the Pasteur Institute, M. Duclaux, evidently believes in the likelihood of the transmission of plague by insects, as among prophylactic measures he advocates the destruction of rats, fleas and bugs. On the other hand, on page 172 of the report for 1898, Müller, of the Austrian Plague Commission which visited India, is quoted as not having found any evidence of the

agency of insects in the conveyance of infection; and in the bacteriological part of the report, since published, Albrecht and Ghon state that they saw no striking mortality among flies, and that in about 700 experiments with animals they never saw infection take place by fleas, flies, lice, &c. They found, however, that flies which had been in contact with infected matter and were then allowed to run about over the surface of an appropriate nutrient medium left germs behind them which developed into colonies of the plague bacillus. On page 182 of the report for 1897 were given the conclusions of Simond with regard to the rôle of insects in the spread of plague. E. Calmette having stated that Simond had "proved that fleas are the chief agent of infection in this terrible disease," Nuttall replied:—

> The fact is that Simond has proved nothing of the kind, and it is altogether premature to accept Simond's generalizations, especially when that author does not know how to distinguish one species of flea from another, and has vague ideas about the mouse-flea and *Pulex irritans* possibly being one and the same insect. The experiments of Simond may be suggestive, but they are far too few in number to base any conclusions upon. A number of experiments made by me have given negative results. Simond rides his hobby to death when he speculates about the possibility of plague bacilli becoming increased in virulence by passing through the body of the flea! He ignores the facts established by my experiments which proved conclusively that various pathogenic bacteria are simply digested in the alimentary canal of the flea. I by no means deny the possibility of virulent bacilli escaping in the fæces, and, in fact, in experiments on bugs have proved that this is the case, but only within the first twenty-four hours after they have sucked infected blood. Numerous experiments on bugs and fleas have shown that *B. pestis*, *B. anthracis*, *B. murisepticus*, and *B. cholerœ gallinarum* die off in the alimentary canal of these insects. Another considerable series of experiments in which these insects were allowed to infect themselves and afterwards bite healthy animals gave uniformly negative results, proving that if this mode of infection is possible, it is the exception and not the rule. Of course, when an insect that has just filled itself with infected blood is crushed upon the skin, and the part scratched, infection may occur . . . . I express the hope that more accurate knowledge will be gained in the future upon the part played by insects, &c., in the transmission of disease agents. It is one thing to establish facts, it is another to write fancies. The time has passed when assertions can be accepted as evidence.

Galli-Valerio also reproached Simond with his ignorance of the flea fauna, and published an article containing descriptions and illustrations of fleas of man, of the rat, and of the mouse. He granted the possibility of the rat and the mouse being infected by their own flea, but pointed out that it had not been shown that the flea of the rat or the mouse could transmit the disease to man. Galli-Valerio also failed to induce the *Typhlopsylla musculi*, the most common flea of rats and mice, to bite himself, or even to remain long on his body; and he mentions that this was not because he is refractory to flea-bites, because the human flea bites him readily. He noted that neither the German Plague Commission in India nor the Italian in Oporto met with instances of the transmission of plague from rats by fleas to man; and added his own opinion that if transmission of plague by fleas is a fact, it is much more probable that the transmission is from man to man by the *Pulex irritans*. Tidswell in Australia is stated to have "confirmed the observations of Simond as to the part played by fleas, and to have demonstrated the existence of plague in the alimentary canal of fleas taken from plague-infected rats"; and "supports the view that, owing to the apparent ease with which the bacillus can be destroyed in nature, plague most likely finds the best mode of dissemination in hosts such as the rat and flea." Nuttall's remarks quoted above may serve as a commentary on the value of Tidswell's find as a proof of insect-transmission of plague. A writer in the *Lancet* says—"Galli-Valerio's rat-fleas would not bite him; but that proves nothing, for no flea will bite the present writer, and many other people, doubtless." He had apparently not noticed that Galli-Valerio, as quoted above from the original article, distinctly states that he is readily bitten by the human flea. Blackmore, again, is of opinion that it is only reasonable to suppose that the species of fleas which do bite human beings are as capable of conveying the disease from a diseased person to a healthy person as the flea of a rat is of conveying it from a diseased rat to a healthy one; and that it is, in fact, judging by clinical experience, extremely probable that vermin play an active part in passing plague on from person to person. It has lately been brought to notice that a hymenopterous insect in Cyprus can transmit anthrax to human beings either by its sting or by accidentally rubbing off on an abraded surface infective material conveyed on its body hairs; and with regard to this Dr. Manson "remarked upon the close analogy between the method of infection in plague and such diseases as this." In a discussion in Berlin in October, 1899, Pfeiffer said that the experiments of Simond were not quite satisfactory, that the whole question was still in obscurity, and that in India no such epidemiological influence of insects had been demonstrable. Sticker considered it doubtful whether rat-fleas ever came on to men. Gärtner pointed out that in general the several races of fleas remained confined each to its own host-genus; but that it was not impossible that they

might occasionally pay short visits to men, have a sample bite, and then go away. Battlehner declared that there were from 60 to 80 races of fleas, that each kind of animal had its own special flea, and that the flea of man was a cosmopolitan, though he was not sure that it went to rats and mice. The general result of the discussion was that the possibility of the agency of insects could not be disregarded, as it was evidently physically possible that they might be directly or indirectly concerned in the introduction of the virus through skin, or in its deposition upon food, implements and furniture. The following appears to give a fairly good account of the present position of the question. It is said to have been written by a member of the German Plague Commission in reply to an inquiry :—

The plague is spread in two ways--first, from man to man : (*a*) by contact, and (*b*) by inhalation ; secondly, from the surroundings of man to man : (*c*) by contact with infected inanimate objects, and (*d*) by the transfer of the contagion from rats to man. We have no difficulty in explaining (*a*) as the penetration of plague germs through wounds or scratches, and (*b*) as the inhalation of minute germ-laden drops of moisture from the lungs of a plague patient. But the second method is less simple. No doubt contact with infected clothes is to be explained as in (*a*). But it is more difficult to understand why living among infected surroundings, *i.e.*, in an infected house, should cause infection without there having been any proved "contact." In this connection we have the disease of rats as an important factor, a factor not similarly observed in the case of any other infectious disease. Rats generally suffer from a form of plague which occurs in man very rarely, if at all, namely, plague of the intestines. When thus diseased they evacuate great quantities of plague germs. It is probable that numbers of plague cases among human beings are due to contact with evacuations of diseased rats, *e.g.*, in the case of the flooring thus contaminated being trodden on by the naked foot. Less probable is the inhalation of such germs in the floor dust, because plague germs are easily destroyed by desiccation. Children often infect themselves by crawling on the floor, and then putting their fingers in the mouth ; thus getting plague with neck buboes. A second possible method in which rats might convey the plague to human beings is by fleas. It is scarcely to be doubted that a flea which has bitten a sick man, and then bites a healthy man, can thus inoculate with the plague ; though it is not clear that this method is as frequent as many investigators, *e.g.*, the French school, are inclined to think. This much is certain, namely, that there are from 60 to 80 different kinds of fleas ; and nearly every animal rejoices in his own particular kind of flea ; so also rats. Now, it is understood that fleas go from beasts to man ; but it is not so certain they will all bite man. No doubt a flea need not actually bite in order to infect. If it causes itching by crawling on the skin, and the person concerned rubs at himself to allay the itching, he may conceivably rub the infected blood from the flea into his own system. It is also asserted that the fleas infesting man are of catholic tastes, *i.e.*, go over to beasts, *e.g.*, rats; and then return, infected, to human beings. Infection by fleas becomes rather doubtful through the fact that in India the relatives of the sick have often, though not sick themselves, been taken to the hospital and have rarely fallen ill, though they most probably have brought fleas in their clothes which might have conveyed the disease from the patients to themselves. It is also on the flea theory of infection not easily intelligible why doctors and nurses are so rarely attacked. The question of infection of plague by fleas cannot therefore be readily answered at present. The fact that when infected houses are once well cleaned and aired they do not give rise to further attacks also speaks against the flea and bug theory, for these are not so readily driven out of houses.

The idea that insects play a part in the propagation of plague is facinating, especially at the present time, and no doubt the supposed intervention of insects seems to explain some otherwise obscure points in the epidemiology of the disease ; but all that can be said at present on the subject must be mere theorizing, on account of the absence of facts. As was said in the report for 1897, however (page 186), there is sufficient suspicion attaching to the possible rôle of insects not only to justify but to call for further research.

Rats.—While from several parts of the world (Asia, Africa, Australia) reports have been received of the discovery of the plague bacillus in the bodies of rats found dead of naturally-acquired plague, and while rat mortality has been noticed in connexion with most outbreaks, yet cases have been recorded both in India and in Europe where there was marked participation of rats, and at the time of a human outbreak in Russia a veterinary bacteriologist is said to have made more than 3,000 post-mortem examinations of rodents without being able to find the plague bacillus.* In fact, the exact connexion between rat plague and human plague has not yet been determined. The soil, articles of food eaten raw, fleas, have been thought of as possible links in the chains of causation, and the benefit of evacuation of affected premises has been ascribed to the fact that the rats are left behind. In a few cases direct infection by the bites of rats has been observed. Clemow, in the course of a very valuable paper dealing, among other subjects, with the relation of rats to plague, says that for the present it must be admitted that rats can and do suffer from plague under natural conditions ; that they can and do act as a means of diffusing infection, and transmitting it to man ; but that the extent to which they are

* The absence of rat infection was supposed to explain the ease with which this outbreak was controlled.

responsible for the diffusion of the disease, and the distance over which they diffuse it, are uncertain; and, finally, that they are an important, but not the sole, means of spreading the disease. It has, therefore, been proposed to wage war against rats with traps, poisons, suffocating gases, artificially induced epidemic diseases. Löffler, Laser, Mereshkowsky, Issatchenko, and Danysz, all isolated from cases of spontaneous disease in mice microbes capable of producing epidemic outbreaks in these animals; but only Danysz so far, apparently, has rendered his microbe regularly virulent for rats. The practical experiments in ridding country-sides of field mice do not seem to have been uniformly successful, and do appear to have required some amount of care and skill; and the question may be, not whether rats are to be destroyed, but whether it is practicable to destroy them. It has been somewhat pertinently asked—"If the plague bacillus, to which rats are so extremely susceptible, does not exterminate the rats, why is it expected that these other microbes will do so?" However, perhaps keeping down the number of rats by the use of a microbe not pathogenic to man, might have some effect in checking plague. On the other hand, it is not known whether the absence of rats might not give opportunity for the increase of some other evil.

Cats, dogs, monkeys.—There is this year, for the first time, some evidence to bring forward to show that cats may occasionally take a part in the spread of plague. Lorans, in Mauritius, mentions that in several cases it was possible to trace infection in the human subject to plague-stricken cats with open cervical buboes, in which, moreover, plague bacilli were discovered. A case, too, is reported from Australia in which a cat was actually found to be suffering from plague, the bacillus being found in the swollen cervical gland. The Austrian Plague Commission succeeded in infecting three cats by feeding, and all developed cervical buboes; and Di Mattei points out that the excrement of infected cats is infectious. Some less definite reports on plague in cats have also been made. The Austrian Commission, too, found the excrement of infected dogs to be dangerous; and, according to Yersin, village dogs have been known to die from eating or biting infected rats. A case has been reported by Hanna of natural infection of a monkey in a state of captivity. The body of the animal was examined in the Bombay Plague Research Laboratory, and the plague bacillus was demonstrated microscopically and culturally in the heart blood and in the tissue of the axillary bubo and of the spleen.

The Bacillus.—With reference to what was said in paragraph 154 of the report for 1898, it may be noted that Ogata has, with the agreement and consent of Kitasato, reported to the Japanese Government that the plague at Kobe was caused by the bacillus of Yersin, and not by that of Kitasato.

Mode of entrance.—One of the most important observations made by the Austrian Plague Commission was the fact that they could infect a guinea-pig, &c., by rubbing without any great force the skin, shaved or not, of one of the hinder extremities with infective material. So readily did infection take place by this method that they were able to use it as a test for the presence of the plague bacillus in suspected material; for example, fæces.

Danger from convalescents.—It has been shown by Gottschlich and by Métin that the sputum of patients may continue to harbour virulent plague bacilli for days or weeks after convalescence has been established.

Endemic centres. Westward spread.—Zabolotny and Clemow have published memoirs on the endemic centres of plague throughout the world. Clemow concludes that the present epidemic of plague started from South China. In certain quarters the fear was expressed that plague might be exported from India by small sailing vessels which ply between Cutch Mandvi and Madagascar, Zanzibar, Mauritius, Jeddah and the Persian Gulf; but no such transport of plague has been proved, and the arrangements at Cutch for the inspection of vessels sailing to ports out of India were, on inquiry in 1899, found to comply with the terms of the Venice Sanitary Convention.

Plague in Egypt.—Instructive reports on the plague in Egypt have been published by the Egyptian Sanitary Department, and also by Gottschlich, an officer of the department, embracing such topics as the origin of the epidemic, the epidemiology (including the part played by rats, in this case not conspicuous), statistics, clinical observations (including a case of injury to the left little finger at a *post-mortem* examination on the 29th May, and appearance of the axillary bubo on the 3rd June; and cases in which the bacillus was found in the sputum of patients many days convalescent from pneumonic plague), bacteriological researches (including diagnosis, degree of virulence, resistance of

the bacillus to unfavourable environment, Haffkine's vaccine, experiments on animals), considerations as to how the bacillus leaves the body of a patient, and, finally, the measures adopted and their effect.

Plague in the Bombay Presidency.—At the end of 1896 there had been a total of 2,909 attacks and 2,086 deaths from plague ; 61,093 attacks and 46,944 deaths were recorded during 1897 ; 1898 saw 110,369 attacks and 86,191 deaths ; while in 1899, as may be seen in the table on page 104, 126,287 attacks and 96,596 deaths were registered. The epidemic continued throughout the year, and was at its lowest intensity in June, and reached its maximum in September. Only one district, Thar and Parkar, remained uninfected throughout the year. The number of towns and villages affected was 2,256 against 1,188 in 1898. The highest ratios of mortality were in the collectorates of Poona (17·94), Belgam (12·63) and Nasik (10·03).

In the Poona collectorate plague occurred in all the talukas. The maximum mortality, 5,947, took place in August. The greatest number of deaths from plague, 10,229, was recorded in the town of Poona, this epidemic of exceptional severity causing the flight of about half the population. The Haveli taluka, in which the city of Poona is situated, returned 5,037 more deaths from the disease. In the city cases occurred in every month of the year, but from May, 1898, up to February, 1899, it is said to have been free from *indigenous* cases, though the occurrence of 37 imported cases caused anxiety. Thirteen of the 37 were detected at the railway station ; seven also came by rail, but were not detected till after the persons had become residents ; and 17 were imported from neighbouring villages. Of the last mentioned 24, five were discovered by means of death certificates, two were found ill on the road, two occurred in an observation camp, and fifteen were discovered by the surveillance system. Every effort was put forth to prevent the establishment of infection, and up to the middle of February no spread of the disease occurred. But in spite of all precautions plague became indigenous towards the end of February, and gradually broke out into the severe epidemic just mentioned. In the whole collectorate 262 towns and villages were affected, and there were 25,239 attacks and 19,047 deaths reported.

As in 1898, the disease was prevalent in Belgam during the entire year. In 1899 it had reached its minimum in April, but from that month it showed an increase till in August the maximum was reached, and for the next two months the mortality was nearly the same, after which a decline set in. The total for the year was 335 towns and villages, 17,875 attacks and 12,772 deaths. Dharwar was affected during the whole year. The year opened with 1,869 deaths in January, and the disease gradually declined till April, when the minimum, 96 deaths, was recorded ; it again increased rapidly, when the maximum, 1,917 deaths, was reached in October ; 382 towns and villages were affected, and there were 12,066 attacks and 9,183 deaths reported. The collectorate of Satara was affected throughout the year, and in all registration circles, except Malcolmpeth. The highest mortality, 2,358, took place in October. Amongst the circles, Karad rural circle returned 2,405 deaths. The town of Karad recorded 908 deaths. In the whole collectorate 298 towns and villages were affected, and there were 12,175 attacks and 8,740 deaths. Nasik was affected during the whole year. From January to June it was to a limited extent, but the mortality suddenly rose from 130 deaths in June to 768 deaths in July, and continued increasing until the maximum was reached in September, when 2,976 deaths were recorded. It declined just as rapidly, and the minimum was recorded in December, viz., 27 deaths. One hundred and fifty-four towns and villages were affected, and there were 10,791 attacks and 8,441 deaths reported. The Thana district was affected during the whole year, as in 1898. In January the disease was on the increase, and this continued until March, when the maximum number of deaths, 970, took place, and then gradually declined until December, when 152 deaths were recorded. The total for the year was 146 towns and villages, 4,996 attacks and 4,362 deaths. The collectorate of Bijapur was affected throughout the year. The disease, which had commenced in September, 1898, was on the increase in December, but in January, 1899, there was a sudden fall, which continued until May, when there were only 5 deaths. The mortality then rose to 12 in June. In July it assumed a greater intensity, and in October it reached the maximum, 752, and fell in November to 535, and in December to 250. In all there were 124 towns and villages affected, and 3,935 attacks and 3,074 deaths. The plague was at its highest intensity in the Kurrachee district in March, April and May, after which it was kept within narrow limits. Kurrachee town circle suffered the most during the year. In the whole collectorate 20 towns and villages were affected, and there were 3,235 attacks and 2,359 deaths reported.

In 14 Native States of Bombay occurred 19,427 deaths from plague; 13,566 in Kolhapur, 1,973 in Cutch, 1,883 in Baroda, and lesser numbers, decreasingly, in Aundh, Bhor, Savanur, Rewa Kantha, Kathiawar, Akalkote, Janjira, Palanpur, Savantvadi, Sachin and Mahi Kantha.

Plague in Bombay City.—As in 1898, the city of Bombay was affected during the whole year. The total for the year was 19,454 attacks and 15,874 deaths. The monthly distribution of the recorded deaths was as follows:—

January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.
1,591	3,118	4,758	2,315	1,008	228	261	348	368	449	436	994	15,874

The maximum was reached in March and the minimum in June. Already in November and December, 1898, the outbreak had begun in twenty of the sections of the city, including Mahim and Worli. In the week ending 3rd January, 1899, it started in Middle and Lower Colaba, Khetwadi, Girgaum, Tarwari and Sewri; in the week ending 10th January in Chukla and Mahalaxmi; in the week ending 24th January in Chowpatti; in the week ending 31st January in Walkeshwar; and in the week ending 7th February in Esplanade. During the outbreak of the first part of the year Fort South and Upper Colaba were but lightly touched, while Esplanade, Mahim and Worli had mortalities approaching double those they had had in the preceding outbreak. With regard to the second half of the year, nothing can be said for want of the Municipal Commissioner's report, which has not yet been received. The above table, however, shows that there was much less plague in the second half of the year than in the first. Some remarks applying to 1899 were quoted from the Municipal Commissioner in last year's report. Up to the 31st December, 1898, 27,887 persons had been inoculated with Haffkine's prophylactic; up to the 27th December, 1899, 113,941; and up to the 3rd January, 1900, 121,206; so that probably about 90,000 were inoculated in 1899. Besides plague, relapsing fever was also present throughout the year.

Plague in the Port of Bombay.—During the year 65,822 vessels of all sorts, with 1,193,339 crew and passengers, were examined. The number includes every person who left Bombay by sea during the year, as well as those who arrived from certain infected ports. Owing to the rigorous nature of the examination and the disinfection of suspicious clothing and bedding, very few fully developed plague cases were found at the time of inspection. The people did not present themselves if they considered they were in any way suspiciously ill. During the year 117 cases of plague were prevented from proceeding on vessels leaving the port, 34 cases were found in vessels and native craft in the harbour and at the docks and bandars, and 4 were found on vessels coming from infected ports close to Bombay; making a total of 155 plague cases. The number of persons who developed plague among those segregated in the camp during the year was 121. Three steamers entered the harbour each with a case of plague on board, and one landed a native passenger suffering from plague at an intermediate port during her voyage from Hongkong to Bombay. Five ocean-going vessels were reported to have had plague on board after leaving Bombay; but investigation left only one genuine case, that of the *Booldana* for Rangoon. At the time of the inspection of the vessel one of the saloon crew, a native cook, was missing. It turned out that the missing cook was at the time suffering from fever on shore, and did not like to face the inspection. He died of plague on shore a few days after the vessel sailed. The man who developed plague on board after leaving the port was another native cook who was found to have resided in the same house as that in which the first cook died from plague. The cook who developed plague on board was therefore a "contact." It is only reasonable to suppose that some of the coasting vessels must have conveyed cases to Kurrachee and the small ports north and south of Bombay; but on the whole they must have been comparatively few. The coast ports south of Bombay, to which the majority of the local passengers go, are free from plague. Kurrachee and Cutch Mandvi are the only ports on the coasts north of Bombay which are infected, and the disease is said not to have left them since the first outbreak in 1896. Unfortunately, plague has broken out at foreign ports, but, so far, no country or port can point to Bombay as being the cause of the plague from which it is suffering; at least in no case can outbreaks at foreign ports be traced to the crew or

passengers from Bombay, The question of infection by rats and cargo has been dealt with by the Indian Plague Commission. The Health Officer of the port continues:—

It is probable that plague of a mild type has been and is widely distributed in the East; and when at times it broke out as a mild epidemic the high mortality was attributed to an unhealthy season or year. At present every one is on the look out for plague, with the result that the true cause of the high mortality which occurs from time to time is recognized as being due to plague. I may mention that plague is endemic on the Arabian coast of the Red Sea between Leith and Lohea and that, owing to recurrent epidemics in October, 1893, July, 1894, August, 1895, and October, 1896, quarantine was imposed at Suez and Aden against arrivals from the infected ports of the Arabian coasts.

Plague in Bengal.—The plague deaths shown opposite Bengal in the table on page 104 belong, with the exception of 583, to the city of Calcutta, and in the same city were recorded all but 756 of the total cases. These 756 cases and 583 deaths were furnished by 16 districts, and in all the places the first patient was found to have come from Calcutta. In the Howrah district there were 162 cases and 111 deaths, confined almost exclusively to the municipality, and mostly of local origin. In the Hooghly district there were 20 cases and 14 deaths, which chiefly occurred in the municipal areas, as Hooghly-Chinsurah, Serampore and Bhadreswar. There were no cases after 5th May. The majority of the cases (106 with 79 deaths) in the 24-Parganas district occurred in the Gossipore-Chitpore municipality, which is practically a suburb of Calcutta, and were reported to be indigenous. Cases from Calcutta also infected the surrounding municipalities. Plague in the district of Dacca was introduced from Calcutta on the 12th February. Between the 15th February and the 3rd March nine other persons, who were infected by contact, died of plague. The disease was carried by a medical man to a neighbouring village. He died on the 23rd February, and between the 24th and 27th there were six other attacks in his house. There were outbreaks in two other villages from infection introduced from Calcutta. Altogether there were 74 cases and 65 deaths. No cases have occurred since May. The disease was introduced into the district of Faridpur by a resident of Bazitpore, who had lived at Hatkhola, Calcutta. He went home ill on the 18th February, and died there the next day. The relations and neighbours who tended him and the medical man who treated him all caught the infection, and communicated it to other persons. Thus by the middle of March the disease had spread to seven houses in Bazitpore, and the infection was carried to Shirkhara, 13 miles distant from Bazitpore. The District Magistrate reported that almost all the cases were pneumonic, and that persons who had attended on their sick relations were generally infected by inhaling the breath of the patients. The total for the district was 32 cases and 30 deaths. Into the village of Jhalwara, about 11 miles distant from the Durbhanga district headquarters, the infection was first brought by two Mahomedans, who arrived from Calcutta on the 7th March. One of them fell ill on the way, and died on the 10th after reaching home; while the other was attacked a day or two later, and died on the 16th. These men communicated the infection to their relations and neighbours; and in all 48 cases and 42 deaths were recorded. Into the Sarun district, wherein 162 cases and 132 deaths occurred, plague was introduced by an Ahir who came from Calcutta, and died of plague in the village of Kutuha on the 22nd January. This was not recognized as plague at the time, and was reported as fever. The next suspicious death in the village did not occur till January 29th. There was one case on February 12th, but deaths did not become frequent till the end of February; and it was not till March 15th that the local authorities heard of the outbreak and visited the village. Altogether, up to 1st April, 86 cases occurred in the village of Kutuha, 72 of which proved fatal. After a lapse of 28 days two new fatal cases occurred in the village, and the revival was believed to be due to infection carried by a dobhi in the clothes of the patients who had died of the plague in Abdul Hai village, where there were 17 cases and 8 deaths in March and April. After the 28th April the district remained free for some months, the disease breaking out again, however, in October, this time at Nayagaon in Sonepore thana. There can be no doubt that the infection came from Kutuha, which is a mile distant. By the end of the month three villages were affected, and 12 fatal cases occurred. Notwithstanding all precautions, the disease gradually spread, and five more villages adjacent to each other in Sonepore thana were affected, 47 cases and 34 deaths being recorded for November and December. The fair at Sonepore, which was close to the infected villages, had consequently to be broken up. In the Patna district were registered 126 cases, two in March, and 124 in December, with 87 deaths. A Hindu male, who on the 8th March had left his residence at Banstollak, a badly infected place in Calcutta, while actually

suffering from plague, arrived in the Patna city on the 9th, and died the next morning. Another case, also imported from Calcutta, occurred in the town of Behar, and ended fatally on the 24th. There was no further case in the district till November, when the disease reappeared in an epidemic form. The epidemic was introduced into Sheikhpura village in the Barh subdivision by a man coming from Calcutta, and it rapidly spread among the surrounding villages. Thus by the end of the year the town of Barh and about 28 villages, mostly in Barh thana, were affected. There was throughout the most determined and systematic concealment of cases and deaths. The other districts affected were Balasore, Shahabad, Tipperah, Nadia, Mozuffarpore, Khoolna, Singhbhum and the Sonthal Parganas. The first two had, respectively, seven cases with five deaths and six cases with six deaths, and the last three, each one fatal case.

Plague in the City and Port of Calcutta.—As the provincial Sanitary Commissioner has failed to furnish an account of the plague in Calcutta for the calendar year, and as the other reports available are for periods other than the calendar year, this paragraph is somewhat difficult to write. Out of the Bengal total of 3,565 cases and 3,264 deaths, 2,809 cases and 2,681 deaths were recorded in Calcutta; but the local plague authorities have reason to believe that the number of cases and deaths was really much greater. The monthly distribution of the recorded deaths was as follows :—

January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.
13	43	770	489	199	49	51	201	202	213	196	255	2,681

From October, 1898, the disease had remained quiescent. Some few isolated cases were reported, which bacteriological examination showed to be plague; and there were a considerable number of cases sufficiently suspicious to lead to the disinfection of the houses in which they had occurred. The mortality during the whole of this period was above the average, and in the opinion of the Health Officer the greater part of the excess was, in fact, due to plague. "It was not, however, till the end of February, 1899, that the existence of plague was sufficiently demonstrated to warrant a declaration that Calcutta was again infected." The city wards most affected in 1899 were, from January to June, III, V, VI, I, XXII, and from July to December, XXII, VI, III, V and IX Major Deane, R.A.M.C., the Special Health Officer, says :—

> It is very clear that during the last six months of 1899, after the epidemic had subsided, the disease was hanging about, and, moreover, doing so in more or less well-defined areas scattered over the city. These areas, in which the majority of plague cases in the 1899 epidemic occurred had their infected foundations laid in 1898. To put the matter in an unconventional way, it looks as though the plague patrols had reconnoitred the city in 1898, and formed outposts, which were reinforced by the main bodies in 1899, and the forces then formed permanent camping grounds, sending out foraging parties into the surrounding neighbourhood, and then retiring into winter quarters. (In parenthesis let me say here, the above facts seem to indicate a plan of campaign: attack the enemy while in winter quarters;

The characteristics selected by Major Deane for special remark, says the Lieutenant-Governor, are the very low contagious and infectious properties which the disease has displayed; and in pursuing the reports the reader cannot fail to be struck by the remarkable contrast which both the mortality figures of the present visitation and the descriptive passages supplementing them present to the records of the various epidemics which depopulated in earlier times the regions they visited. With regard to the part which rats play in the epidemiology of plague, Major Deane is of the following opinion :—

> So far as Calcutta is concerned, up to the present there is no evidence that rats have had anything to do with the spread of plague, much less that they have been the chief mode of dissemination. So far from the human population having originally contracted infection from rats, the evidence is clear that rats have become infected after human beings, or contemporaneously with them, from a common source. As the epidemic grew worse, so did rat mortality become greater. If we knew how human beings get plague, we should know how rats get it, and *vice versâ*, perhaps.

Three hundred and nine vessels arrived in the port of Calcutta during the year from the plague-infected ports of Bombay, Kurrachee, Hongkong, Penang, Mauritius and the Hedjaz; but no cases of plague were found on any of these vessels. It appears also that no cases were found in the port or in vessels leaving it.

Plague in the Punjab.—The plague mortality statistics of the Punjab for 1899 are given in the table on page 104. The following is condensed from the report of Captain James, I.M.S., the Chief Plague Officer. The province had been reported free of the disease on the 20th September, 1898 ; but the village of Kariam was discovered to be infected on the 1st October, 1898, and from that date until September 9th, 1899, a succession of plague-infected villages came under observation and treatment. This second recrudescence of the disease was much smaller than the first epidemic. It was confined to a much smaller area, and fewer villages were infected. There were only 26 villages attacked in the Jullundur and five in the Hoshiarpur district. There were altogether 408 cases during this period, of which 220 proved fatal. Of these cases 359 occurred in the Jullundur district, and 213 were fatal. In the Hoshiarpur district occurred 49 cases, of which only 15 terminated fatally. The disease in the Jullundur district had still its former virulence and tendency to spread ; but the authorities were able to get much earlier information of the villages being infected than in the previous year, and in this way many places escaped with few seizures. With a few modifications, the measures adopted were the same as in the previous year. The chief feature of the year's epidemic was certainly the evacuation and disinfection of the comparatively large town of Rahon. The question as to whether plague can lie dormant in a village without cases of illness appearing has not yet been settled. In the case of Kariam it is believed that the disease existed in a mild form among the sweepers some time before it was discovered. Of the 31 villages which were attacked during the season in the two districts, nine suffered last year. In none of these could any evidence be obtained pointing to the disease being a recrudescence. In most of them there was clear evidence of the disease having been reintroduced from a neighbouring recently-infected village. In the other cases the disease appeared in a fresh quarter of the village and among a new class of the inhabitants, and usually avoided parts infected the previous year. The manner of infection from one village to the next was usually by human agency. But there are one or two facts which were very prominent throughout the epidemic, and are somewhat difficult to explain. The most noticeable was that women were almost always the first persons affected, even when men were suspected of being the means of bringing the infection. Another interesting point was that the first cases very frequently occurred on the outskirts of the village, even in cases in which the entrance to the mohalla was a road leading right through the village. The outlying infected mohalla in many cases faced the last infected village. Numerous cases came to notice where rats seem to have been the media of carrying infection from one part of the village to another. But this year there were no clear cases in which it could be traced that the infection had been brought by rats from another village. In one or two cases, *e.g.*, Shikopur, rats appear to have died before the people got attacked, but in these cases there was also a history of clothes (probably infected) having come from an infected village. In 28 villages of the Jullundur district 8,465 inoculations against plague were performed, and 719 in seven villages of the Hoshiarpur district. Some interesting points as to the effects of inoculation arose for consideration. The temper of the people was throughout admirable. They have come to appreciate the efficacy of the measures carried out for their benefit, especially evacuation of houses. In several cases they had begun to come out into camp before the plague authorities arrived in the village.

Kariam village in the Jullundur district.—Late in the evening of October 1st a report was received that plague had appeared in Kariam, a village situated about three miles south of Nawashahr, and between the villages of Bhangal, Ghataron and Hansron, which had been affected during the early part of the year, though Kariam itself up to this time had escaped. Captain Wilkinson, the Plague Medical Officer, visited the village the following morning, and discovered two Chamar boys in adjoining houses, who had well marked symptoms of plague. A woman living in the next adjoining house was beginning an attack of plague. On further inquiries being made, it transpired that at least two other persons had previously suffered from symptoms which were most probably those of plague. Up to the time the village was evacuated all who were attacked were Chamars, and all belonged to the same family. The whole village was evacuated by October 5th, and the systematic disinfection of all the houses completed by the end of the month. But, unfortunately, three persons were attacked with plague. These men had all been working in the village between October 24th and 29th ; but they had worked in different parts and only at whitewashing, which is the final stage of the operations, and succeeds the disinfection of the houses with chemical disinfectants. This pointed naturally to some defect in the measures taken. Live rats were seen when the

disinfection was first started. None were seen as the disinfection reached completion. Several dead rats were found during the operations, but Dr. Wilkinson was unable to satisfy himself that they had died of plague. When the village was redisinfected between the 7th and 27th November, in consequence of the occurrence of the cases just mentioned, more dead rats were found, though very few. Finally, after the second disinfection was completed, and before the people returned to their homes, live rats again began to make their appearance in the houses. Since, there has occurred an almost parallel case in the village of Bhangal, in which the cause could be traced, and which appears to furnish a clue to this case. At any rate it gives the only hypothesis which has any facts to support it, viz., that rats can and do reinfect the houses after they have been disinfected.

Langari village in the Hoshiarpur district.—From the 9th October, 1898, to the 8th April, 1899, there was no case of plague in the Hoshiarpur district. On the 8th April, village Langari, situated a mile and a half to the south-west of Mahilpur, and inhabited principally by Jat Sikhs, was found to contain three cases of high fever in a family of four who left Shikopur on or about the 28th of March, 1899. Mussamat Gulab Devi, one of the members of this family, and who only remained free from plague, said that a few days before her departure from Shikopur she found dead rats in her house there, and from last year's experience of Shikopur she was sure that plague would appear in the village. These three cases of Langari were subsequently found to be genuine plague cases; and it turned out that Mussamat Gulab Devi's son was the first plague case at Shikopur.

Plague in the North-Western Provinces and Oudh.—The plague statistics of the North-Western Provinces and Oudh for 1899 are shown in the table on page 104. With the exception of a couple of imported cases, one at Moradabad in February and one at Mau (Azamgarh) in November, neither of which gave rise to further cases, the provinces remained free from plague up to nearly the end of the year, when an outbreak took place at the village of Mau Amia, about 22 miles from Allahabad. In this village out of a population of 6,301, nearly a quarter are weavers, many of whom are habitually employed in Bombay, but have been recently obliged to return to their homes, owing to the contraction of the cotton industry. Among these a man named Khizir, with his son and daughter, arrived in Mau Aima on the 23rd of November, 1899, and the son was taken ill and died early in December. There is some uncertainty as to the date of his death, but it appears unlikely that he was actually infected at the time of his arrival. The assumption is that he became infected after his return, through the agency of clothing brought with him. The infected portion of the village was evacuated, houses wherein cases had actually occurred were burned, and all possible measures put in force; and these precaution appear to have been successful in confining the outbreak to a small number of persons, but dropping cases were still occurring up to the end of the year, the total number of seizures being 11, with six deaths. Inspections at border stations were steadily maintained throughout the year.

Plague in the Central Provinces.—In the table on page 104 are given the plague statistics of the Central Provinces for 1899. The total number of deaths was 584, against 131 in 1898. Cases of indigenous plague occurred in only two districts, Nagpur and Wardha. In the former, the first outbreak was discovered on the 16th February in Circle IV of the Nagpur city; though it was afterwards ascertained that deaths which there was good reason to ascribe to plague, had been occurring there for some 11 days previously. Both before and after the official recognition of the disease, the people left the infected locality in considerable numbers, and scattered themselves in the suburbs of the town, mostly in garden houses. Several deaths occurred in these places, but none of them became *foci* of the disease, and the outbreak appeared at the end of February to have been completely checked. On the 12th March, however, the disease broke out in Circle III, and from that date till the 6th May cases continued to occur in various parts of the town; generally, but not always, in the vicinity of the circle originally affected. The disease, which was probably imported from Wardha, never during this outbreak assumed the character of an epidemic. From the 7th May till the 12th August the city of Nagpur remained free from plague, but on the latter date the disease again made its appearance and continued till the end of the year. The first discovered case was in the person of a Brahman mendicant, named Mutanah, residing in Circle VII. Although Mutanah was not known to have left the city or visited an infected area for some weeks before his illness, the locality in which he lived had been under observation for some days, as several deaths of a suspicious nature had occurred there. It was subsequently

ascertained that a number of pilgrims had gone to the Pandharpur Fair, in the Sholapur district, and returned to Nagpur about the end of July, some of them having also visited Poona and Bombay before doing so. One of these pilgrims, named Baija Bai, soon after her return fell ill in Circle VII, and died on the 4th August in a house in Circle IV, to which she had been removed two days before, the period of her illness extending over a few days. Some other suspicious deaths occurred shortly after in the house adjoining the one in which she was attacked, and a further death of a similar nature took place on the 18th August in the house in which she died. The above circumstances, coupled with the fact that a further period of 16 days from the discovery of the first verified case, the extension of the disease was confined entirely to Circle VII, that for some time this circle furnished a preponderating proportion of cases, and that the areas affected in the former outbreak had not been specially attacked in this one, appear to indicate that this second outbreak was due to reinfection, and not to recrudescence. The outbreaks which began in the towns of Hinganghat and Wardha in the last quarter of 1898, continued in the first quarter of 1899; and it was during the prevalence of these epidemics that six villages in the Wardha district became infected in the early part of the year. The district, however, remained quite free of the disease from May to October. But in November there was a fresh outbreak in Hinganghat, the source of infection on that occasion having been traced to one Hiraman Kumbar, who, with his family, left Nagpur in October for Hinganghat, where he put up with the Kumbars of that place. Shortly after his arrival he and several members of his family were attacked with plague, from which they died. The disease then spread among the neighbours; but the outbreak was of short duration, terminating on the 19th November. About this time a number of Kumbars from the Hinganghat infected locality went to Pulgaon, where, shortly afterwards, three fatal cases of plague occurred amongst them and their caste-fellows. The necessary precautionary measures were adopted, with the result that no fresh cases occurred.

The measures at first taken to prevent the spread of the disease were those detailed on page 187 of the report for 1898. On the 17th September a public notice modifying the rules in force were issued to the following effect:—

(1) No plague patient shall be removed to the plague hospital unless he or his friends consent.

(2) No contacts shall be removed to the segregation camp against their will, and they may continue to live in the infected house if they prefer to do so. But, if they decide to leave it, they must undergo the usual period of segregation in the camp before settling elsewhere.

Shortly afterwards the restriction regarding compulsory segregation of contacts before settling elsewhere was removed, and the disinfection of persons and clothes substituted.

As soon as possible after the outbreak of plague a supply of Haffkine's prophylactic fluid was obtained from the laboratory in Bombay; and in the hope of inducing the people to resort to inoculation, and of removing any prejudice which existed against it, a notice in Hindi and Marathi was widely distributed. Altogether 4,331 inoculations were performed.

In most of the verified instances in Nagpur the disease was of the bubonic type; but in other localities whither the disease extended from this source it appears to have assumed a more virulent character, and the pneumonic form became the prevailing one.

Mortality among rats did not at first come to the notice of the officials; but the Sanitary Commissioner was informed that some of the natives in the plague camps had confessed that they had been in the habit of secretly burying dead rats found in their houses, to avert suspicion of infection. Afterwards their discovery became more common.

Plague in Mysore.—The statistics will be found in the table on page 104. The epidemic which commenced in Bangalore city on the 12th August, 1898, and in which some 6,000 lives were lost, almost completely subsided in March, 1899; and during the months of April and May there were no indigenous cases, so that the city was practically free for two months. In June it recrudesced, and the numbers steadily increased up to the end of the year. What the cause of the recrudescence was it is impossible to say. In Mysore city, which was first affected towards the end of October, 1898, the epidemic reached its height in February, and from that date it gradually declined. The epidemic never assumed such a serious character as in Bangalore, but this is attributed by the Sanitary Commissioner to the fact that no less than 29,000 persons were inoculated

before plague assumed an epidemic form. It may be said with safety, thinks the Sanitary Commissioner, that plague is now more or less endemic in the cities of Bangalore and Mysore. Of the remaining districts, only Kolar, Tumkur and Chitaldroog were infected. In the district the remedy is evacuation ; and, as the people are well aware of its benefits, little or no persuasion is necessary to get them out. Inoculation was very little resorted to. The class of people who are chiefly affected by plague are the poor, ill-clothed, and underfed, who live in dwellings devoid of fresh air and sunlight, and whose sanitary surroundings are of the worst description.

Plague in the Madras Presidency and in Madrâs City.—The general plague figures for Madras are given in the table on page 104. The following is shortened from the report of the Sanitary Commissioner. The total attacks in the presidency for the whole year amounted to 2,385, with 1,843 deaths. The plague epidemic, which had commenced in the last quarter of the previous year in the Deccan districts of Anantapur, Bellary and Kurnool, showed marked symptoms of diminution in March, and had completely disappeared within the first three weeks of May. In these districts there had occurred a total of 70 imported and 716 indigenous cases, with 56 and 588 deaths respectively. In the North Arcot district plague lingered up to a later date ; indigenous cases did not cease till the end of June. In this district there were 67 imported cases with 55 deaths and 647 indigenous cases with 501 deaths. In the Hosur taluk of the Salem district, however, although from May to June there was exhibited a decrease of indigenous cases, plague manifested a continued, though not severe, prevalence throughout the year. In December a second taluk in the Salem district was attacked. This followed a severe outbreak in the municipal town of Tirupattur, owing to a lamentable want of discretion on the part of the municipal authorities. The total imported cases in this district were 141, with 88 deaths, and the total indigenous cases 682, with 508 deaths. Kollegal taluk of Coimbatore was subjected to a short epidemic outbreak extending from October 7th to December 16th. In this district there were one imported and 47 indigenous cases with 37 deaths. Imported cases were also reported in Chingleput, Nilgiris, Trichinopoly, Nellore and Madras town. In none of these instances was importation followed by indigenous plague . . . So far in this presidency not a single instance has been recorded of what would be correctly understood as recrudescence. Indeed, were it not for the continued presence of plague in the Hosur taluk of the Salem district—a condition that may well be ascribed to the free intercourse which exists with the neighbouring infected Mysorean villages—it might be said that villages that have been once affected have escaped fully any recurrence . . . There was no change of the policy with which Government met the requirements of plague administration during the year. The method of detection trusted to has been that of inspecting travellers by road, rail, and sea, on routes communicating with infected areas, isolation of the sick, and requiring the healthy during the periods of possible incubation to be subject to surveillance whilst in no way restricting their movements. The district board, municipal, and village organisations lend themselves to the successful effecting of this scheme . . . It has been arranged that *before* starting from an infected village the inhabitant should obtain a passport, which, under the usual rules, will secure his surveillance whilst travelling beyond its limits . . . A system which demands that at certain points an uneducated native should be given a piece of paper, by which it is required that he should present himself for a period of 10 days to the plague authority at any village or town at which he may halt, may seem well-nigh visionary ; yet experience shows that under this simple method the free population may be allowed to pass from one end of the presidency to the other with fair assurance that both the passport-bearer and the local officer will fulfil their duties. By means of this system a large number of the imported cases have been detected at the very onset of the disease, and thus the possibility of spread has been enormously minimised. Of course, it has not been possible to ensure that all passport-holders should have been put under surveillance ; still, the amount of success which has attended the endeavour suffices to prove its great utility . . . A fair example of what can be done, even in large towns, is illustrated by results obtained in the municipality of Madras, where failure to trace passport-holders occurred only in 3·4 per cent. of 55,407 cases . . . It must be admitted that introduction of plague is possible by cases that have eluded surveillance ; yet the figures are so enormously in favour of successful surveillance, that no one can feel otherwise than that the system is of distinct practical value . . . In towns much passive opposition to evacuation of infected houses has been exhibited ; but in rural areas the benefit of rapid evacuation is often so well recognised that on the occurrence of plague there is a general exodus to encampments on clean sites outside the town. An officer of

the Indian Medical Service having adversely criticised the bacterial purity of haffkinine before the Plague Commission, the educated native public lost faith in anti-plague inoculation. As a result only 5,955 persons were inoculated during the year.

Plague in Hyderabad State.—The plague death statistics for Hyderabad will be found in the table on page 104. At the end of the year 1898 plague was declining throughout the Nizam's dominions, and this improvement continued with a slight upward fluctuation in March, during the first five months of 1899, so that in May the lowest number of attacks and deaths for the year was reached. It was hoped at the beginning of June that the epidemic would be entirely got under, but the disease increased in June in the Lingsugur district, and in the same month the district of Gulburga was infected from the little state of Akalkote. In July the epidemic had thoroughly revived in both districts, and it continued to increase until September. In October, November and December it declined again. The total number of cases was 7,887 against 4,475 in the previous year. On the 1st of January, 1899, there were 27 villages infected with plague in the Nizam's dominions. Nine of these were situated in the zilla of Naldrug, adjoining the British collectorate of Sholapur. Eighteen villages were infected in the Lingsugur taluq, adjoining the British collectorates of Bijapur, Dharwar, and Bellary. The infected districts were therefore 200 miles apart, and separate plague measures had to be instituted for each. The infected villages in the Naldrug district threatened the large trading town of Gulburga on the Great Indian Peninsular Railway, and those in the district of Lingsugur the equally important railway junction of Raichur; and through these two towns Hyderabad itself was menaced. In neither place did plague effect any lodgment, though 16 cases of the disease were imported into Gulburga. There is no doubt that the reason why Gulburga and Raichur escaped was that adequate arrangements were made by the Subadar of Gulburga and the Taluqdar of Raichur to prevent its importation and spread. The total number of villages infected in the year 1899 was 186 against 71 in 1898 and four in 1897. In 1898 three villages were re-infected, and in 1899, 13. In every one of these cases the reinfection was due to re-importation, and not to the survival or revival of the old infection. The measures employed to deal with the epidemics of plague in the State in 1899 were the same as those which were successful in 1898. In the first place every infected town or village was promptly evacuated, and the inhabitants made their own arrangements for camping out in the fields. By this time it had come to be recognised by the people themselves that by evacuating their homes they left infection behind them, and they cleared out with alacrity when plague became indigenous, and were ingenious in making themselves comfortable at little or no expense in grass huts of their own construction in the fields. The villagers in the Hyderabad State are now, also, fully alive to the advantage of keeping infected persons out of their villages, and almost every village employs a sort of quarantine of its own, whereby people from infected areas are kept out of the villages until the period of incubation has passed. Inoculation with haffkinine was commenced in April, 1899, in Kuppal. It was also carried on during the year in the Lingsugur and Naldrug zillas. There were in all 4,308 inoculations, and there would have been more had not the supply of fluid become exhausted.

There is no doubt that plague infection is spread by human agency, and it was principally in this way that it was carried about from village to village in the Nizam's dominions in 1899. The infection having been conveyed into a house, says the Plague Commissioner, the house becomes infected. The virus appears to be deposited in the floors, which constitute the principal medium by which plague infection is propagated from one human being to another, as well as to animals which are susceptible to it. While there is no doubt that the germ of plague is carried about in, and liberated from, the bodies of human beings, it is still an open question as to the exact part played in the propagation of the infection by the lower animals, especially rats. Rats are very readily affected by the plague bacillus, and die rapidly when they are inoculated with it. It is not yet, however, known positively what part they play in liberating and spreading the infection.

Plague in Rajputana.—For Rajputana were returned 29 cases and 24 deaths; but it is stated that only nine attacks and eight deaths were diagnosed with certainty as due to true plague, the rest being merely suspicious cases. The cases were returned from the Jodhpur, Sirohi, Pertabgarh and Mewar States. With regard to Pertabgarh, it is mentioned in a special report that altogether the nature of the outbreak remains obscure; and it is suggested that it was perhaps epidemic sore throat accompanied by enlarged glands, such as occasionally occurs in oriental villages, the result of bad water and insanitary surroundings.

Only one case, an imported one, was reported from Ajmer-Merwara.

Plague in Berar and in Central India.—The first case in Berar was imported from Ahmednagar. A female passenger alighted at the Mana railway station, and travelled by cart into Amraoti town, arriving there on the 3rd September. The case was discovered, segregated, and treated. The woman died on the 6th. All necessary precautions were promptly taken both at Mana and at Amraoti, and the disease did not spread. The second case, a suspicious one in the town of Amraoti, also proved fatal in the same month. Arrangements for the inspection by hospital assistants of passengers alighting at railway stations were in force during the year.

The two cases that occurred in Central India were imported from British territory. They were segregated, and no spread of the disease followed.

Plague in Burma.—The regulations regarding the medical inspection of incoming vessels from plague-infected localities were carefully carried out, and all cases of fever and suspicious cases generally were segregated under observation till their temperatures became normal. Two cases of plague were removed from vessels, the first from the s.s. "Buldana," from Bombay, in the person of the ship's cook. This vessel carried no passengers. The man was removed to the plague hospital, died, and was cremated. The vessel was thoroughly disinfected, and quarantined for ten days. The second case was that of a follower of the West Riding Regiment which arrived in Rangoon from Bangalore on the 17th October. A follower found with high fever was detained under observation, and the regiment allowed to disembark. Later on plague symptoms developed, and the man died in the plague hospital, where he was cremated. As soon as the case was pronounced one of the plague the troops and followers were at once segregated in camp and the vessel disinfected and quarantined. No other case occurred.

Fevers.

The fever-mortality ratio of India for 1899, though below that of the quinquennium, was somewhat above that of 1898; and the number of deaths rose from 3,868,781 to 4,126,384. The maximum months of death were December, November and October, and the minimum month February. There was a reduction in the number of deaths in each of the first three months of the year, and an increase in each of the other months. Though five provinces had ratios greater than in the preceding year, only two had mortalities higher than the quinquennial ratios. The highest ratio was that of the North-Western Provinces and Oudh. The greatest reduction from the quinquennial mortality was in the Central Provinces, and the greatest increase in Ajmer-Merwara.

The following table shows the mortality from fevers in different provincial registration areas of India in 1899 month by month :—

Statement showing the deaths from Fevers registered in the different Provinces by Months during the year 1899.

PROVINCE.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	TOTAL.	RATIO OF DEATHS PER 1,000 OF POPULATION.

* Excluding Zamindaris.

It seems strange that so many as six out of the 13 provinces should have had the rural mortality lower than the urban; probably the rural registration was at fault. But, at the same time, the highest provincial rural mortality registered was that of the North-Western Provinces and Oudh, which usually have the rural mortality below the urban. The highest district ratio in India was that of Goella in Ajmer-Merwara, and it also showed the highest increase over the ratio of the preceding year. The greatest percentage of rural districts with high mortality was in the North-Western Provinces and Oudh, and the same administration had also the greatest percentage of towns with high mortality, as well as the highest general urban mortality in India. The town with the highest ratio and with the greatest increase over the previous year was Umarkot in the Bombay presidency. From fevers there were seven deaths among the European seamen in the port of Calcutta, six from enteric and one from malarial fever, and 37 among the native floating population. Similar statistics for Bombay are not forthcoming. In the city of Bombay relapsing fever was present throughout the year.

Sale of quinine at Post Offices.—In Bengal there was an increase in the number of quinine five-grain pice packets sold during 1899 to the extent of 859,146, against a considerable falling off in the two years preceding. This is considered to have been most probably due to the greater prevalence of fever almost all over the province. In 29 out of the 39 districts which returned a higher mortality from fever there was a corresponding increase in the sale of quinine. The sale of quinine was larger during every month of 1899, except January; the total sale for the year being 3,337,236 five-grain pice packets.

In Assam, as might have been expected, owing to the improved general health, the sale of quinine through the agency of the vaccination and post office staff fell off considerably, 2,286 packages against 3,750.*

At post offices and by vaccinators in the North-Western Provinces and Oudh were sold 136,982 pice packets. Yet the largest amount of quinine sold in any district amounted to but something under 62 grains for each thousand of the population.

Mention is made of gratuitous distribution of quinine in the Punjab districts of Dera Ghazi Khan, Dera Ismail Khan and Hoshiarpur. The Civil Surgeon of the last named district stated that the experiment of selling quinine in pice packets had proved a failure.

The Central Provinces, Berar, Bombay and Madras do not appear to have furnished particulars of quinine sales, if such there were.

By the post offices in Coorg 23,218 powders were sold, nearly one-third less than in the preceding year. On the 26th of December, 1897, the price of one powder was raised from two pies to three pies, and to this the Civil Surgeon principally attributes the great falling off in the demand for quinine powders.

The Sanitary Commissioner states that the scheme for the sale of quinine in the interior of Burma does not appear to have achieved much success. The Burman villager is said not to appreciate quinine; and though some are willing to use the drug if given to them, yet few wish to buy it, preferring their own remedies. In some instances Deputy Commissioners reported that the use of the drug was unpopular, and recommended that the scheme should be given up altogether. The Sanitary Commissioner, however, thinks that it would be a pity to abandon it without further trial, and without further endeavour made by the district authorities to popularize the drug.

Remarks by provincial Sanitary Commissioners.—Of the remarks made on the subject of fevers by the Sanitary Commissioners of the various provinces the following are some of the most interesting:—

Bengal.—The Civil Medical Officer of Malda says:—"The marshes are the unhealthiest features of the district. If fever is to be combated, these should be reclaimed. They should be drained dry and made to grow not rice but wheat, a dry crop and not a wet one. With the marshes the miasmata will disappear, and with wheat health will appear; for in a malaria-stricken country rice as a staple article of food should be eschewed." The Civil Medical Officer of Dinajpur is of opinion that the chief cause of the fevers is malaria due to excessive sub-soil moisture; and states that in his district there are about 674 square miles of marsh land, about one-sixth of the entire area. At Murshidabad, Rajshahi and Faridpur it appears that the want of sufficient rainfall and of floods at places during September and October, by failing to wash away impurities and wash out tanks and other sources of water-supply, seems to have generally rendered the last quarter of the year most unhealthy.

---

* *i.e.*, probably 233,172 and 382,500 five-grain pice packets.

Assam.—The number of deaths from the fever known as *kala azar*, district by district, and year by year, is shown in this table :—

Districts.	1893.	1894.	1895.	1896.	1897.	1898.	1899.
1	2	3	4	5	6	7	8
Cachar	2	1	—	1	—	—	1
Sylhet	30	2	9	4	—	3	—
Goalpara	623	384	265	298	232	134	161
Kamrup	2,490	2,149	2,059	2,244	2,756	1,693	1,745
Darrang	1,620	1,992	2,477	2,471	3,597	4,113	4,101
Nowgong...	5,407	8,585	11,037	10,588	12,102	10,515	8,192
Sibsagar	1	2	5	4	2	9	8
Lakhimpur	50	36	30	16	12	3	3
Nagar Hills	—	—	—	—	—	—	—
Khasi and Jaintia Hills (selected areas) ...	24	13	12	11	1	2	5
Garo Hills (selected areas)	—	—	—	—	—	—	30
Total	10,247	13,164	15,891	15,637	18,612	16,472	14,246

On the whole, the epidemic may be said to be surely, if slowly, ceasing; but whether it will disappear without infecting the Sibsagar and Lakhimpur districts is more than any one can predict. The Deputy Commissioner of Sylhet made some inquiries as to the prevalence of the fatal fever called "*mulki pira*" in allusion to the way it spreads over the country, or "*pet mota*" from the enormous enlargement of the spleen which characterizes it, a fever which has been severe for the last two or three years in the tract between Sylhet and Fenchuganj and Balaganj . . . In my opinion these cases must be considered as *kala azar*, as I am not acquainted with any other kind of fever which produces such symptoms and results. The Deputy Commissioner got one village to remove to a new site in the open fields, to try if this would stop the effects of "*mulki pira*"; the villagers stated that they had lost numbers in the last three years, but that since removal to their new site the disease had almost disappeared.

Punjab.—There was no unusual rise in the mortality during the autumn months. This was due undoubtedly to the dryness of the season, being the result of failure of the monsoon, the rainfall registered in the third quarter of the year being only 7·77 inches against an average of 17·53 for the preceding ten years. It is probable that many deaths registered as "fevers" are caused by influenza.

Berar.—The increase was general in all districts . . . Influenza, which was very prevalent in 1899 as compared with 1898, especially at the end of the cold and commencement of the hot weather, served to increase the mortality under this head.

Madras.—The rate was the smallest recorded since 1883. Unfortunately it cannot be assumed that this is due to any striking measures taken for the reduction of malaria. Quinine has been successfully issued at post offices, and there have not been wanting those who have hunted the *anopheles:* but no great measures that would effect removal of superfluous mosquitoes, or moisture that would encourage their existence, from large areas, have yet been carried out. Rather must the reduction be regarded as due to the imperfect character of the north-east monsoon failing to bring with it the essential presence of moisture in the soil, and to the not insignificant influence of a desire on the part of those registering deaths to escape suspicion of a disease whose prominent symptom is fever, namely, plague. Although it is well known that the majority of these "fevers" are of malarial origin, doubtless phthisis, pneumonia, pleurisy, affections of the liver, and diseases generally where fever is the prominent symptom are included under this rough head . . . Some effort is being made to secure a better approach to accuracy in municipalities . . . There is no lack of instances in this presidency where a locality in which mild fever has existed has been converted into a deadly malarious place by introduction of superfluous water for irrigation purposes, and there are instances where limitation of irrigation has been followed by beneficial results, but none where extensive works of drainage have secured the admirable curative influence obtained in other countries . . . During the year Major Grant, I.M.S., Professor of Hygiene, invited attention to the severe nature of malarial fevers found in Madras town . . . Not only does malaria exist in Madras itself, but intense forms are to be found within seven miles of it at Ennore—a once favoured health resort, in which disturbance of sub-soil and surface water was brought about by railway and canal configuration. In 1896 I spent several days here, and obtained ample microscopical evidence of the presence of the *plasmodium malariæ* in its various forms, in subjects who had indubitably acquired the disease locally. It must not, however, be considered that malaria is the sole cause of fever in Madras town. Typhoid fever is by no means uncommon. Phthisis and low forms of pneumonia are prevalent among the poorer classes. There are doubtless also hitherto unclassified fevers to be demonstrated by the observer of the future.

Burma.—It is usual for the mortality from fevers in rural circles to exceed that of town circles, the explanation being that dwellers in the country are more exposed to malarial influence than the residents of towns . . . Swampiness and various other sanitary defects are noted by the Civil Surgeons of the five towns in which mortality was above the average under this heading. . . . Though the term "fever" covers a multitude of complaints in which a rise of temperature occurs, and deaths other than those due to malaria are often registered under this heading, still, as similar errors in classification occur pretty equally in all districts, the deaths recorded under "fevers" may, for purposes of comparison, be regarded as of malarial origin, as doubtless the majority of them are, and may be taken as a test of the malaria-producing condition of the tract of country to which they refer. For the five years 1894–98 the fever death-rate of Burma was, next to that of Madras, the lowest in India.

Dysentery and Diarrhœa in India.

The mortality ratio for bowel-complaints for India, though lower than the quinquennial figure, was higher than in 1898, and the number of deaths rose from 216,321 to 252,025. The maximum month of death was August, and the minimum February. January and February showed a decrease, all the other months an increase as compared with the corresponding months of the year before. All the provinces but three had higher ratios than in 1898, but only five had ratios higher than the quinquennial mortalities. Much the highest ratio was that of Berar, and next came the ratios of Bombay and Assam. The greatest reduction from the quinquennial mortality was in the Central Provinces, and the greatest increase in Ajmer-Merwara; exactly as was the case with fevers.

The following table shows the mortality from dysentery and diarrhœa in the different provincial registration areas of India in 1899 month by month :—

Statement showing the deaths from Dysentery and Diarrhœa registered in the different Provinces by Months during the year 1899.

PROVINCE.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	TOTAL. 1899.	RATIO OF DEATHS PER 1,000 OF POPULATION. 1899.	1898.

* Excluding Zamindaris.

Only in Berar was the rural mortality higher than the urban; and in this province both the rural and the urban mortality were the highest in India. The highest district ratio of India was that of Akola in Berar; but among maximum district ratios the greatest increase over the ratio of the previous year was in Jassakhera in Ajmer-Merwara. The greatest percentage of rural districts with high mortality was in Berar, 100 per cent. The town with the highest ratio and with the greatest increase of ratio was North Lakhimpur in Assam. The greatest percentage of towns with high mortality was in Berar and Assam. In the port of Calcutta there were three deaths among European seamen, and five in the native floating population. There are no corresponding figures at hand for Bombay.

Remarks by provincial Sanitary Commissioners.—Some of the more important remarks of the Sanitary Commissioners of the various provinces on the subject of bowel-complaints are as follows :—

Bengal.—The increased prevalence of dysentery and diarrhœa was probably due to some extent to the causes which led to increased cholera in many districts, viz., early cessation of the rains and the early pollution of the water-supply . . . The intensity of the disease was as usual much greater in towns than in rural areas. This seems to be chiefly due to overcrowding and and its attendant evils, which are more intense in towns than in the open country; and also to the greater probability of the disease being correctly diagnosed and reported in towns.

Assam.—The district rates present the same extraordinary and unaccountable differences as in former years. The difference must, I think, be more apparent than real, and be caused by differences in registration. I cannot believe acute bowel-complaint to be more than 23 times as common in Lakhimpur as in Goalpara.

Berar.—The deficient and impure water-supply would account generally for the increase in this disease.

Madras.—The highest proportion of mortality for districts from this cause was, as usual (if the town of Madras be excluded), in Chingleput. It is presumed that, in addition to the usual causative agents of dysentery and diarrhœa, there exists in that district a favouring cause in the brackish water used by a considerable proportion of the population. The towns which returned the highest mortalities are towns either where conservancy is defective, or in which the water-supply is open to contamination : and frequently these two defects are combined with a brackish condition of the water. Variations in the registered amount of dysentery and diarrhœa from year to year are brought about by the occurrence of cholera, when doubtless attempts are made to conceal the existence of this disease, or, more especially at the beginning and end of such epidemics, mistakes in diagnosis occur ; but on the whole, from year to year there is, broadly speaking, little material change of the death-rates from dysentery and diarrhœa in any special town. There is little tendency to epidemic outbreak. On the contrary, where bowel affections have established themselves they seem to claim their victims at fairly regular rates from year to year, proving that permanent, not passing, sanitary defects are at work.

Bombay.—Up to 1897 the deaths ascribed to dysentery and diarrhœa showed only comparatively slight variations, but in that year they rose from 36,046 to 85,966 ; and though they fell in 1898 to 56,789, they rose again in 1899 to 74,736 . . . The increase was most noticeable in the parts affected by famine. The collectorate of Sholápur headed the list, and ratios were also high in Khandesh, Poona, Nasik, Satara, the City of Bombay, and Bijapur. In the Gujrat District also there was an increase in every collectorate, but the figures are not high, considering that the district is famine-stricken.

Burma.—The prevalence of epidemic cholera is generally reflected in the mortality registered under diarrhœa and dysentery ; but it is to be noted that Tavoy and Thatôn returned comparatively low death-rates from cholera, so that the cause of the high mortality from bowel-complaints must be sought for in some other direction.

Injuries.

The recorded deaths from injuries rose to 98,593 from 95,291, and the ratio to 0·45 from 0·44. There was an increase in the number of deaths from the attacks of snakes and wild beasts, and from injuries other than the suicidal, there being a decrease in suicide. The increase of mortality from total injuries was greatest in Madras and Bengal. The Sanitary Commissioner of Bengal says :—

> The disastrous floods which occurred in the Godda Subdivision of the Sonthal Parganas and in the eastern portion of the Bhagalpur district on the night of Sunday, the 24th September last, and the terrible landslip at Darjeeling about that time, are responsible for the increased mortality from "accidents." It is curious that while the total number of suicides committed from year to year is pretty constant among both sexes, nearly twice as many females every year perish by this means as males. This, however, is quite opposed to facts observed in England and Scotland, where a much larger number of males than females—nearly thrice as many of the former as the latter—resort to self-destruction. As compared with the women of Great Britain, the women of this country occupy a lower position in society, and their grievances are believed to be many, while political and mercantile excitement and dearness of food that are such potent causes of suicide in Great Britain are, especially the first two, almost absent in this country.

It is noted that the districts of Azamgarh, Hardoi, Farakhabad, and Shahjahanpur in the North-Western Provinces and Oudh, and of Gurgaon in the Punjab, have usually the largest number of suicides in their respective provinces. In the Punjab there were 111 deaths from hydrophobia, against 147 in the previous year. In the Bombay report it is mentioned that deaths from snake-bite were, as usual, most common in the rains. In the Central Provinces arrangements have been made to have the necessaries for the antivenene treatment ready at all dispensaries.

All other Causes.

There was an increase in the number of deaths registered under the heading "all other causes" from 1,376,725 to 1,748,689, and in the ratio from 6·31 to 7·92. The extent to which plague is, either openly or for purposes of concealment, included under this head, varies in the different provinces. The Sanitary Commissioner of Bombay is inclined to think that a new column should be added to the registers for diseases of the respiratory organs. The greatest increase was in Berar, Bombay, and the Central Provinces. In Bombay the increase is ascribed to better registration.

Vaccination.

The work of the Vaccination Department in India during the year 1899–1900 is represented by a total of 8,125,337 operations among the civil population of the country. This must be considered a satisfactory result, as it indicates a return to ordinary conditions after the considerable decline exhibited in the returns of the two preceding years. The aggregate number which stood at 8,019,836 in 1896–97, fell to 7,829,983 in 1897–98, and still further to 7,515,527 in 1898–99, owing mainly to the presence of plague and famine. The directions in which these causes operated need not be discussed here at length, but it is obvious that famine, by raising the death-rate of infants and by lowering the birth-rate, leaves less material to work upon ; and as regards plague, its actual presence and the fear of its invasion not only diverted the services of officers and subordinates to other pressing work, but it gave rise among the people to unfounded fears that vaccination was being used as a cloak for anti-plague inoculation. Plague unfortunately is still amongst us, but the dread it inspired has greatly diminished, and the measures for its suppression are generally accepted with more or less equanimity. A striking instance of the returning confidence of the people is afforded by the year's work in the small province of Coorg, where operations returned to the normal after having fallen off 50 per cent. the year before ; elsewhere a similar experience is afforded, if not in such marked degree.

The numbers of both primary cases and re-vaccinations show an increase, the aggregate excess over the figure of the preceding year, amounting to 609,810 cases, being contributed to in varying measure by all the provinces without exception. Of primary operations there were 7,500,113 against 6,931,793 in 1898–99, and of re-vaccinations 625,224 as compared with 583,734. The degree of success secured in the former rose to 94·63 per cent. from 93·87 per cent. in 1898–99, but in re-vaccinations, on the other hand, it fell from 63·71 to 58·76 per cent. ; this is less a matter for regret if it connotes the increasing efficacy of primary operations and a higher standard of work and verification.

In regard to primary vaccination, the degree of success secured by the special staffs in the several provinces varied greatly ; Ajmer-Merwara heads the list with 99·08 per cent., followed by Assam with 98·81 ; while Madras takes the lowest place with 91·8 per cent., the Bombay results, which are the next lowest, being 92·68 per cent. In re-vaccination the range is still greater, and while Ajmer-Merwara again occupies the first place with 90·83 per cent. of success, the next in order is Assam with 88·56, until we come to 40·39 in Bombay and only 17·2 in Berar. As has been pointed out in previous reports, extreme differences in results must be due in the main to divergence in the interpretation of the term " successful." Enquiries instituted to elucidate this point have shown that such is actually the case, the rank and file of the Department exercise too little discrimination, and, in practice, use a very varying standard in determining this important but simple question. It goes without saying that the standard for both primary operations and re-vaccinations should be one and uniform, and steps are being taken to ensure this in future, as at present the results are not comparable, and are indeed often incomprehensible.

The staffs of the dispensaries conducted vaccination operations in all the provinces save in Berar and Ajmer-Merwara, and the success secured by them ranged, in primary cases, from 97·25 per cent. in the North-Western Provinces and Oudh to 66·57 per cent. in the Punjab, and in re-vaccinations from 92·19 in Assam to 48·83 in Bengal. As a natural result of the increased total of operations performed during the year, the ratio of persons who may be regarded as protected from small-pox rose from 30·26 per 1,000 of population in 1898–99 to 32·86 in the year under report. These figures are, however, necessarily only approximate, as the population must have generally increased since the census of 1891, the figures of which are used in the calculation. The provincial ratios of population protected ranged from 56·72 in Burma and 54·70 in Coorg to 29·49 and 28·72 in the Bombay and Madras Presidencies, respectively. Berar again heads the list as to the average number of operations performed by each vaccinator, the number having risen from 3,020 in 1898–99 to 3,997 ; the Punjab comes next with 3,150 ; Bengal again returns the lowest figure, viz., 596, which is an increase of 10 on the result of the preceding year. In Berar rewards varying in amount from Rs. 45 to Rs. 20 were given to six vaccinators in recognition of the excellent work performed during the year, which was far above the average.

With the increased outturn of the work by the Department, the number of children under one year of age successfully vaccinated increased in every province as compared

with the results of the preceding year. The aggregate number amounted to 3,462,702 as compared with 2,815,592 and 2,853,132 in 1897–98 and 1898–99 respectively. Assuming a hypothetical birth-rate of 40 per 1,000 of the population, the protection afforded to infant life is represented by a ratio of 38·11 per cent., while in the two years immediately preceding it was 31·37 and 30·95 ; this ratio ranged from 83·00 in Berar, where it was also highest in 1898–99 with 60·31 per cent., to 11·70 in Coorg, which also occupied the last place in the preceding year with 7·38 per cent. The total number of children between the ages of one and six years successfully vaccinated again showed a fall ; in this report for 1898 it was noted that the number had declined from 3,172,881 in 1897–98 to 3,008,037 in 1898–99, while in 1899–1900 it was 2,990,364. The decrease occurred in all provinces save the Punjab, Madras, Coorg and Ajmer-Merwara, and is probably to be attributed to the increased infantile mortality due to scarcity and famine, and to a lower birth-rate in 1896 and 1897.

The ratios of deaths from small-pox in the calendar years 1898 and 1899 were 0·26 and 0·23 respectively per 1,000 of the population. No marked epidemic during the year under report (1899) was traceable to inoculation, which appears to linger in Bengal, Assam, the Punjab, Bombay and Burma, but is only general throughout the last-named province, and in Assam is said to be fast dying out.

The following statement shows in outline the working of the Department in the several provinces during the two years 1898–1899 and 1899–1900, *i.e.*, the year under report and that preceding it :—

Comparative statement of Vaccination in the different Provinces of India, in 1898–1899 *and* 1899–1900, *together with the death-rates from Small-pox during* 1898 *and* 1899.

PROVINCE.		Population.	NUMBER OF VACCINATIONS PERFORMED.			PERCENTAGE OF SUCCESSFUL CASES.		Persons successfully vaccinated per 1,000 of population. * Calculated on the figures taken from the Sanitary Reports.

† Refers to special Vaccination Establishment only.

Animal Vaccination.—During the year bovine lymph, either pure or in combination, was used in all the provinces, humanised lymph being resorted to in addition only in the

Punjab, the Central Provinces, Burma, and the North-Western Provinces. It may be noted that no precise information is afforded as regards the lymph used in the Bombay Presidency, except that animal lymph was exclusively used in Bombay City, and also in certain places in the Western and Central Registration Districts and in some Native States. The obvious disadvantages attending the use of human lymph is recognised in Burma, and orders have been issued for its discontinuance as far as possible.

Glycerinated lymph appears to have met with marked success and is used exclusively in Assam, where its results are remarkably good. This lymph is also used in Bengal, the Central Provinces, and Madras. As regards the last province, it is said that glycerine is employed more as a diluent than a preservative, and that to secure the best effects it is necessary to use the combination fresh and as soon after preparation as possible. The percentage of success secured in rural areas, 88·5, against that in towns, 95·2, is instanced in support of this contention, and it is held that glycerine paste gives results approximately equal to those of fresh animal lymph if used when quite freshly prepared, but that the results are inferior in proportion to the delay which may occur in its use. Against this, it was found in Assam that such lymph, kept for over six months, was as efficacious as at the time of manufacture. But it should be noted that in Assam the vaccine matter is scraped from the abdomens of the vaccinifers and pounded up with a mixture of glycerine and water in the proportion of two parts of solid matter and one part each of glycerine and water, and put up in capillary tubes which are hermetically sealed by fusing their ends in the flame of a spirit lamp; this procedure tends to maintain the potency and to obviate the contamination of the lymph with extraneous micro-organisms. Details of manufacture are doubtless all important to the results secured, and certainly the Shillong lymph has passed out of the stage of trial into that of well-approved excellence. It is of interest to note that a supply of two thousand tubes was set aside from the vaccine manufactured in February, 1900, for an experiment during the season 1900–1901, to determine if the lymph will keep its properties unimpaired through a hot weather in the plains, and the result will be awaited with the interest its importance demands.

As regards the Central Provinces, it was noticed in this report for 1898 that the use of glycerinated lymph had not been attended with success. At the instance of the Sanitary Commissioner with the Government of India, a further trial was made during the year under review, with more satisfactory results, the percentage of success secured having been 86·27, as compared with 72·69 in 1898–1899. Hence it is probable that in the essential details of preparation something was wanting which experience has supplied.

In Berar only lanolinated lymph was used, the year's work being started in September 1899 with a supply obtained from Mysore. Owing to the famine, healthy calves could not be obtained in sufficient numbers to carry on calf vaccination, and the only alternative was that resorted to. But to obtain the total requirements of lanolinated lymph from Mysore would have proved unduly costly, and it was therefore decided to manufacture it at Amraoti. This arrangement contributed largely to increase the amount of work done, as it obviated the necessity of taking vaccinated calves from one place to another, but it had also the result of reducing the degree of success attained. This decrease is attributed to (1) the lanolinated lymph containing proportionately less vaccine than pure calf lymph, and (2) to the locally manufactured lymph losing its efficacy according to the distance it is sent, with the delay and exposure involved. Although the expedient was necessary in an emergency and is creditable to the Sanitary Commissioner, pure calf lymph is to be reverted to as soon as circumstances permit. Lanoline lymph was also used to some extent in Bengal, the Central Provinces, and the North-Western Provinces, but the results are not stated.

Vaseline lymph appears to be used only in the Punjab; the Deputy Sanitary Commissioner is of opinion that there is no doubt as to the efficacy of this paste in producing scars that present that foveated appearance which is maintained to be the best test of efficient protection.

Generally, then, it will be seen that bovine lymph, either pure or in some combination, is fast displacing humanised lymph, and it may be hoped that in a comparatively short time the latter will find no place in vaccination operations.

For the rest some details of the comparative results of the use of bovine lymph and its various combinations will be found in the following paragraphs which deal with the details of vaccination in the several provinces.

Bengal.—The Sanitary Commissioner was, as usual, in charge of the Vaccination Department during the year 1899–1900. The staff employed under him comprised three Deputy Sanitary Commissioners, the 48 civil surgeons employed in the province, 207 native supervising officers, and six head vaccinators ; and working under this controlling agency were 65 vaccinators employed by Government, 87 by district boards, 245 by municipalities and at dispensaries, 3,440 licensed vaccinators and 1,199 apprentices. It should be noted that though the Western Bengal Circle was in charge of an assistant surgeon throughout the year as Deputy Sanitary Commissioner, the Northern Circle was without an inspecting medical officer from the 1st April to 28th December, 1899, the Sanitary Commissioner himself attending to the current duties of this office in addition to his own. Moreover, the three officers appointed to the Metropolitan and Northern Bengal Circles were otherwise employed, two of them on plague work, and one on an inquiry into the sanitary condition of the riparian municipalities north of Calcutta. As a consequence of these special calls these officers were unable to inspect vaccination work.

Throughout the province the total number of operations performed was 2,252,521 as compared with 2,147,452 during the preceding year, an increase of 105,069 operations ; but with this increase on the provincial total there was a decrease in the number of operations in 21 districts, the chief causes alleged being the prevalence of cholera and malarial fevers of a fatal form ; the decrease ranged in different places from 9,243 in Dinajpur to 302 in Angul. On the other hand, there was a notable increase of 26,222 cases in Mymensing, and of 23,526 in the Sonthal Parganas.

Over the whole province the number of primary operations was in excess of that of the preceding year to the extent of 116,699 cases ; the number of successful results was 2,152,824 as against 2,045,384 during 1898–99, an increase of 107,440 ; but the ratio per cent. of success was 97·67, being slightly less than that attained in the year preceding, when it was 97·99.

In 1898–99 the number of successful re-vaccinations reported was 40,520, which showed a decrease on the results of 1897–98 of 8,687 operations. There was a still further fall during the year under review to a total of 24,071, and the percentage of success was only 49·59 against 67·34 in 1898–99.

No satisfactory explanation has been furnished of this large decrease, and as regards Dinajpur where the falling off is most marked, the civil surgeon merely attributes it to the unwillingness of the people to submit to re-vaccination.

With regard to the vaccination of infants, the hypothetical birth-rate has, in accordance with the orders of the Local Government, been taken at 50 per 1,000 of the census population, though elsewhere the accepted rate is 40 per 1,000, and this has necessarily reduced the calculated proportion protected to 16·79. But taking the birth-rate as in previous years at 40 per 1,000, the degree of infant protection afforded was 21·81 per cent. as compared with 17·66 per cent. in the year preceding, and 16·7 the mean of the three years 1895–96 to 1897–98.

The Sanitary Commissioner notes that the results in the municipalities are unsatisfactory, considerably less than half the available number of infants being protected, and in spite of the fact that the Compulsory Act is in force.

The average number of persons vaccinated by each vaccinator was 596 against 586 in the preceding year, an increase of 10, but considerably less than the figure for 1897–98, when it was 650.

The Deputy Sanitary Commissioners of the Metropolitan and the Eastern Bengal and of the Northern Bengal Circles, being unable to devote any time to the duty as already explained, the work of inspection by these officers could not be undertaken. In Western Bengal the Deputy Sanitary Commissioner found 97·61 per cent. of the operations inspected to have been successful, but the number inspected was only 2·25 per cent. of the number performed. In five districts the number of cases inspected by civil surgeons exceeded 10,000 in each, an amount of supervision which was only accomplished in two districts in 1898–99 ; in nine districts, as compared with seven in the previous year, between 5,000 and 10,000 cases were inspected. In six districts, against four in the preceding year, there were less than 1,000 inspections made. The percentage of operations to the total performed, inspected by civil surgeons was, however, 9·30 against 8·51 in the previous year, and this is nearly equal to the result in 1897–98, when it was 9·34. District and sub-inspectors inspected 39·29 and 64·65 per cent. of the total performed as compared with 39·70 and 67·8 in 1898–99.

As noted in last year's report, direct calf-to-arm vaccination is steadily gaining ground ; the primary operations in 1899–1900 numbered 241,831, an increase of 35,748 over the figure for the previous year (206,083), and which was 31,082 in advance of that for

1897–98. Re-vaccinations, however, by this method numbered only 10,196, or less than half the total of the previous year, which also showed a falling off from the results of 1897–98.

A total increase of 48 is reported in the number of calves operated on at both the Calcutta and Darjeeling depôts, while the amount of lanoline paste manufactured at the animal vaccine depôt, Calcutta, increased by 2,866 grains ; the outturn of the Darjeeling depôt, however, declined to the extent of 4,247 grains. The cause of this decrease has not been stated, though the matter is of interest and importance, since the number of calves operated on at this depôt was larger by 20 than that of the year preceding, and, moreover, the supply of lanoline lymph paste from this depôt to the Sikkim State, which received 405 grains, is reported to have proved eminently successful, though the exact results have not been given.

Assam.—The staff of the Department was practically the same as in the year before, viz., 19 inspectors and 186 paid and 23 licensed vaccinators, working under the control of the Sanitary Commissioner and district civil surgeons ; the number of apprentices employed was 11 compared with 7 in 1898–99. The work of this staff was, as usual, supplemented by that of medical subordinates at and near dispensaries, and by private practitioners on tea-garden estates.

The total number of operations performed by all agencies during the year was 272,265 against a total of 258,905 last year, and of this number 255,131 were primary operations and 17,134 re-vaccinations. The percentage of success secured was 98·50 and 88·90 respectively, and the Sanitary Commissioner, who in the previous year was inclined to doubt the accuracy of these results, now practically accepts them as approximately correct, as it has been abundantly proved that the lymph supplied from the Shillong depôt is of consistently excellent quality ; this, however, does not dispose of the doubt to which the results recorded for re-vaccination is open.

Paid and licensed vaccinators and apprentices performed in the aggregate 236,031 operations against 232,419 in the previous year, and the dispensary staff 24,715 against 14,271. The percentage of success obtained in the primary cases and re-vaccinations represented by these figures was 98·81 and 88·56 respectively for the paid and licensed staff, and 97·16 and 92·19 for the dispensary establishments. This satisfactory increase on the results of the previous year was unfortunately not shared by all districts, a large and unexplained falling off having taken place in the Naga Hills and the Khasi and Jaintia Hills. Manipur and Kamrup also show a decline ; in the latter, the reason assigned is the replacement of licensed by paid vaccinators. On the other hand, the spread of vaccination in the Garo Hills is remarkable ; the number of operations in 1895–96 was 5,287, rising in 1898–99 to 15,866, until, in the year under review, no less than 28,071 cases were recorded. This is a striking evidence of what can be achieved by a zealous officer in a single district.

The Compulsory Vaccination Act continued in force in 11 towns, but the fall in the number of operations was continued, from 3,487 in 1897–98 to 3,021 in 1898–99, and to 2,752 in the year under report. No explanation of this marked decline has been afforded, but as a result of 595 notices issued there were only 22 prosecution in Sibsagar, with no convictions ; obviously such a lax state of affairs cannot be expected to improve the unsatisfactory condition of vaccination in compulsory areas.

On an estimated birth-rate of 40 per 1,000 the protection afforded to infants was 27·02 per cent as compared with 22·36 in the previous year, and 22·4 the mean of the three years preceding 1898–99. Taking the total number of successful operations, 46·62 per 1,000 of the population at all ages were protected against 45·02 in the previous year, and 49·61 in 1897–98.

The inspection work accomplished cannot be considered satisfactory, though it is recorded that district civil medical officers increased the total number of their inspections from 22,577 to 27,277. Nevertheless the percentage of cases inspected to the total number vaccinated was only 10·46 per cent. against 9·15 in the preceding year, and the increase is entirely due to the efforts of one officer. The work of the native inspecting staff leaves much to be desired, the number of inspections having steadily decreased, viz., from 150,005 in 1897–98 and 133,681 in 1898–99 to 121,660 in the year under report. The percentage to total vaccinations represented by these figures is 55·0, 54·19 and 46·65 respectively.

The percentage of successful cases approved by civil surgeons and native inspectors was 96·81 and 98·50, respectively, as compared with 95·99 and 98·73 in 1898–99.

The practice of inoculation is fast dying out, and no epidemic of small-pox was traced to its survival. Arm-to-arm vaccination has also been abandoned throughout the whole province.

The work of the animal vaccine depôt at Shillong was again attended with success, the quality of the lymph being uniformly of a very high standard. Calves to the number of 330 were inoculated and from these 317,382 tubes were loaded, the total expense incurred being Rs. 7,753. This number of tubes was somewhat less than in the preceding year when the outturn was the largest on record. An outbreak of rinderpest among the calves necessitated work being suspended for 10 days, but there was no stoppage of the supply of lymph owing to the precaution of keeping a fortnight's supply in hand.

In consequence of the success attending operations with a supply of glycerinated lymph which had been kept for six months, experiments are being made to ascertain its keeping qualities. It will be interesting and important to ascertain if lymph will retain its efficiency if kept in the plains throughout a hot weather if not exposed to sunlight, but the results will only be available for publication in the ensuing report.

North-Western Provinces and Oudh.—Vaccination operations were conducted in the united provinces, as usual, under the supervision of the Sanitary Commissioner, two Deputy Sanitary Commissioners, and 48 civil surgeons, who are styled district superintendents, and 49 native assistant superintendents, the controlling staff being thus the same as in the preceding year. The average number of vaccinators employed throughout the province was 898 or 23 more than during 1898–99.

The number of operations performed was 1,511,436 against 1,398,684 in the preceding year, an increase of 112,752, and of the total 1,449,653 were primary cases and 61,783 re-vaccinations; a satisfactory increase in both classes as compared with the work of 1898–1899. Of these 1,365,931 and 47,292 respectively were successful, the percentage of success being returned at 97·00 and 81·93 respectively, in cases in which the results were known. This is an improvement on the results for the two preceding years, viz., 94·96 and 79·76 in 1898–99, and 93·74 and 68·20 in 1897–98, in the two classes of operations respectively. The average number performed by each vaccinator was 1,683·11, a commendable increase as compared with recent years, the figures being 1,598·5 in 1898–99, and 1,598·9 in 1897–98.

At dispensaries 891 primary operations were performed with a percentage of success of 97·25, against 525 operations and 90·02 per cent. of success in 1898–99; there were also 30 re-vaccinations by this agency, with a percentage of success of 44·00 against 71·43 the previous year.

There were 853,065 infants successfully vaccinated during the year, so that taking the birth-rate at 40 per 1,000 of the census population, 45·24 per cent. were protected against 33·80 per cent. the year before, and a mean of 30·04 in the three previous years.

The Vaccination Act is in force in all municipalities and cantonments, but is enforced with a very varying degree of energy. Steps have been taken to direct the attention of the authorities concerned to the matter where necessary, and it is hoped this will have a beneficial effect where the rules are perfunctorily observed. There was, however, an increase of 14,828 successful primary vaccinations in these towns, as compared with the total for the previous year, and the proportion of persons protected rose from 33·1 per 1,000 to 37·97.

The actual total number of cases inspected by the Deputy Sanitary Commissioners and civil surgeons increased to 134,614 cases from 129,403 in 1891–99, and similarly the assistant superintendents verified 456,379 operations against 411,165. This gives a percentage to the total number vaccinated of 8·91 and 30·19 for 1899–1900 as compared with 9·25 and 29·40 in 1898–99, by the two classes of inspecting officers respectively specified. The results given show that superior inspecting officers found 96·97 per cent. successful, and inferior inspecting officers 95·08, as compared with a ratio of 96·41 per cent. claimed by vaccinators.

The lymph supply from the Almora and Garhwal depôts is reported to have been very good, while that from Tehri-Garhwal was unsatisfactory, and many tubes of the latter supply were rejected by the Deputy Sanitary Commissioner. Measures have been taken to improve matters. Besides these there were three other minor depôts at work, one each in Lucknow, Allahabad and Bahraich; the supply from the latter was good, but that issued

from the first only gave satisfactory results locally, but not so when sent elsewhere. It is suggested in explanation that the crude lymph does not retain its efficacy for any length of time under conditions of exposure.

The results of the lanoline calf lymph supplied to municipalities from the Allahabad depôt were found by the Deputy Sanitary Commissioner to be most disappointing. In this case the cause is attributed to inadequate supervision of the details of manufacture, and steps have been taken to remedy defects. The question of a central bovine lymph depôt, to be located in the hills, was still under consideration at the close of the year.

Punjab.—The strength of the Department was precisely the same as in the preceding year, and consisted of the Sanitary Commissioner, the Deputy Sanitary Commissioner, the district civil surgeons, six divisional inspectors, 24 native inspectors, and 303 vaccinators.

The total number of operations performed in the province was 943,074, an increase of 102,206 over the figures for the previous year. Of these 744,917 were primary cases and 198,157 re-vaccinations, compared with 661,937 and 178,931 respectively during 1898–99.

The district, special and cantonments staffs all show an increase in the work of primary vaccination, and the district and cantonment staffs in that of re-vaccination, compared with the results of the preceding year. The dispensary staff, however, performed less than half the number of primary operations to its credit in 1898–99, 344 cases against 808, though re-vaccinations were increased from 335 to 407.

The general provincial increase noted above is satisfactory, the total number of operations being the highest recorded for many years. The system instituted last year, by which the vaccinators work in groups instead of as isolated units, and to which, as a new departure, a falling-off in the results was attributed in the previous year, has now been developed more effectually, and appears to be fully justified. In contrast to this general improvement a decrease is noted in the work in eight districts, but this is mainly as regards re-vaccination, and various local and special conditions are declared to be responsible for what is doubtless only a temporary decline. The decrease in the work of the dispensary staff as regards primary operations is due to the fact that medical officers in charge of dispensaries are only permitted to vaccinate those who may attend for the purpose, and this number shows a tendency to diminish as confidence in the itinerant vaccinators developes.

Over the whole province the percentage of success gained in primary vaccination is recorded as 94·68, as compared with 94·84 in 1898–99; but the results attending the few operations performed by the dispensary staff exhibit a decline from 85·59 to 66·57 per cent. in 1898–99 and 1899–1900 respectively. In re-vaccinations the whole provincial percentage of success was 62·55 in 1899–1900 against 58·80 in 1898–99.

Of the Native States which maintain their own vaccination staff, eight, against seven in the year before, furnished returns; in these States 92,981 primary cases and 36,845 re-vaccinations were performed, and to these figures the Patiala State alone contributed 56,413 and 35,654 respectively. The total shows an increase of 8,434 primary operations, but a decrease of 5,661 re-vaccinations, the latter result is no doubt largely due to re-vaccinations having been suspended during the year in the Nabha and Jhind States. The percentage of success in primary cases ranged from 98·07 to 92·21, and in re-vaccinations from 100·0 in Bahawalpore and Maler Kotla, to 40·63 in Kapurthala.

On a hypothetical birth-rate of 40 per 1,000 of the census population of the province, 66·55 per cent. of the infants born were protected, an increase on the calculated results of the previous year, when the percentage was 59·97, and over the mean of the three years preceding 1898–99, which was 58·2 per cent.

The work of inspection performed by civil surgeons and native supervisors shows an improvement. The former verified 9·39 per cent. of the total primary operations, and 6·27 of the whole number of re-vaccinations, against 6·54 and 3·38 per cent. respectively in the previous year; the latter officers inspected 65·4 per cent. of the total primary cases, and 35·51 per cent. of the re-vaccinations, their figures for 1898–99 being 60·14 and 35·21 per cent. respectively. Divisional inspectors verified 16·54 and 15·73 per cent. against 17·81 and 15·29 in 1898–99. The percentages of success reported by the supervising staff were, as in the year before, in all cases higher than those reported by vaccinators.

The lymph in use was of three kinds, viz., animal, human, and vaseline paste, and the percentage of success secured in primary cases was 99·31, 99·27 and 96·81 per cent. respectively, as compared with 99·20, 99·37 and 93·6 in the preceding year. In re-vaccinations the results were: vaseline paste 80·10 per cent. against 70·92 in 1898–99

animal lymph 77·75 against 73·65, and human 68·52 against 75·71. Vaseline lymph was more extensively used and with better results than in the previous year ; it is expected that as vaccinators learn to apply this vaccine the results will improve. The deputy sanitary commissioner is carrying out experiments to determine the protective power of this compound by subsequent operations on the same subject repeated at varying intervals ; comparative results from pure bovine lymph will be ascertained.

The animal lymph depôt was located at Murree from April to October inclusive, and at Amritsar for the rest of the year, viz., November to March. Of vaseline vaccine paste, which is the only lymph prepared at the depôts, 1,847 and 3,468 tubes were manufactured at Murree and Amritsar respectively, which represents a total increase of 2,149 tubes on the outturn of the preceding year ; only 48 tubes are reported to have failed against 53 the year before. The expenditure incurred in maintaining the lymph depôt was only £51, and it is calculated that sufficient paste for each vaccination was produced at a cost of less than one pie.

Central Provinces.—The only change in the strength of the Vaccination Department in the Central Provinces was an increase of three in the number of Native Superintendents of whom there were 31. The rest of the staff consisted of the district civil surgeons and 274 vaccinators, all under the control of the Sanitary Commissioner.

The total number of operations performed during the year was 484,535, or 49,361 more than in 1898–99 ; the increase in primary cases was 65,672, but there was a decrease of 16,311 in re-vaccinations, and the difference amounts to the net increase noted.

The total of primary operations numbered 436,704 against 371,032 in 1898–99, 60,366 of the increase being apportioned to British territory, and 5,306 cases to Feudatory States. In re-vaccinations both areas exhibit a decline to the extent of 10,535 and 5,776 respectively, a total decrease of 16,311 cases, there having been only 47,831 re-vaccinations in 1899–1900 as compared with 64,142 in the preceding year.

As regards primary cases, the percentage of success in British districts was 96·65, and in Feudatory States 95·82 as against 96·82 and 92·86 respectively the year before. The results for re-vaccinations are returned at 81·32 and 92·42 per cent. in the separate areas respectively as compared with 79·15 and 95·70 in the preceding year.

The average number of persons vaccinated by each vaccinator rose creditably to 1,767 from 1,391 in 1897–98, and 1,588 in 1898–99.

The primary operations in British territory numbered in all 354,655, of which 342,782 were returned as successful, the percentage being 96·65, which was slightly less than the result secured in the previous year, when it was 96·82. Re-vaccinations numbered 41,739, of which 33,941 were successful, yielding a percentage of success of 81·32 against 79·15 per cent. in 1898–99.

In the Feudatory States primary operations amounted to 82,049, of which 78,616 were successful, compared with 76,743 and 71,263 respectively in the previous year. The percentage of success claimed being 95·82 in the year under review, against 92·86 in 1898–99. Of re-vaccinations there were 6,092 against 11,868, and the percentage of success was 92·42 and 95·70 in 1899–1900 and 1898–99 respectively.

In addition to the above there were 24,788 operations performed at dispensaries during the year, an increase of 10,712 compared with 1898–99 : of these ,18,166 were primary cases in British territory, and 1,987 in the States, with a percentage of success of 92·87 and 91·79 in the separate areas respectively, against 94·03 and 91·51 the year previous. Re-vaccinations numbered 4,578 against 1,411 in 1898–99 in British territory, and 57 against 64 in Native States, the percentage of success returned being 75·01 in British territory and 75·43 in the States, against 61·45 and 87·50 respectively the year before.

Calculated on an estimated birth-rate of 40 per 1,000, 60·18 per cent. of the infants born in the year were protected, against 44·61 in 1898–99, and 44·3 the mean of the previous three years.

The visitation of famine affected the important work of inspection, which was more or less confined to relief camps, and, as a consequence, the returns show a decline in this respect as compared with the preceding year ; it is stated, however, that "on the whole, inspection work was performed in a satisfactory manner." Civil Surgeons verified 15·99 per cent. of the total number vaccinated, and native superintendents 50·95 per cent., against 17·19 and 53·35 respectively in 1898–99. The percentage of successful cases approved was however higher, viz., 92·27 in the cases examined by Civil Surgeons, and 95·02 by Native Superintendents, as compared with 89·08 and 92·19 respectively in the previous year ; the vaccinators themselves claimed 96·65 per cent. as successful.

As in the preceding year the operations were done with humanised lymph, fresh calf lymph, and calf lymph mixed with lanoline and with glycerine. The degrees of success secured by the various kinds of lymph have again not been stated comparatively, but it is satisfactory to note that the use of glycerinated lymph, which in the previous year's report had been declared unsatisfactory, was given a further trial at the suggestion of the Government of India, with far more satisfactory results, a percentage of success of 86·27 being attained against 72·69 in 1898-99.

Berar.—The staff of the Department was precisely the same as that of the preceding year, viz., seven native superintendents and 44 vaccinators, and it worked up to its full complement under the control of the Sanitary Commissioner.

The total number of operations performed was 175,901, an increase of no less than 42,998 over the figure of the previous year; primary cases numbered 120,772 and re-vaccinations 55,129, against 94,032 and 38,871 respectively in 1898-99. The causes of this satisfactory increase are attributed to the high birth-rate, to the influx of unvaccinated persons due to the famine, the accessibility of children on relief works, and the use of lanolinated lymph.

The average number of operations performed by each vaccinator which stood at the high figure of 3,020 in 1898-99 rose to 3,997, and this excellent work was suitably acknowledged by rewards to six of the vaccinators.

The total number of successful primary operations numbered 115,789, and of re-vaccinations 9,522, compared with 91,286 and 8,989 respectively in the preceding year, which represents a percentage of 95·8 and 17·2 against 97·1 and 23·1 in 1898-99.

Assuming a birth-rate of 40 per 1,000 of the census population, 83·0 per cent. of those born are calculated to have been protected, a result largely in excess of that achieved in 1898-99 and during the quinquennial mean, for which the figures were 60·31 and 62·8 per cent. respectively.

The Sanitary Commissioner inspected 1·0 per cent. of the total primary operations against 2·06 in the previous year, and native superintendents 50·3 against 55·6 per cent.; the percentages approved by these officers as successful were 98·2 and 94·2 per cent., while the vaccinators claimed 95·8 per cent. of success.

Work was commenced in the middle of September with a supply of lanolinated lymph, obtained as usual from Mysore, the supply being maintained by calf-to-calf or arm-to-calf inoculation. Owing, however, to the famine, difficulty was experienced in procuring suitable calves for the latter procedure, and the only alternative was to resort to lanolinated lymph. To obtain all the paste required from Mysore would have been very costly, and the Sanitary Commissioner therefore arranged for its manufacture, in November, at Amraoti. The result of this arrangement was to produce the necessary supplies at a very considerably lower cost, and to admit of a larger number of operations at any one time or place, as the necessity for carrying calves from place to place was obviated. But the degree of success resulting from this paste was lower than that secured by the direct use of pure calf lymph, and has induced the Resident at Hyderabad to express the hope "that calf lymph will be reverted to as soon as circumstances permit."

Madras.—The Vaccination Department in this Presidency was as usual under the general control of the Sanitary Commissioner, assisted by the deputy Sanitary Commissioner, and the district medical and sanitary officers. The actual operating staff consisted of 61 deputy inspectors inclusive of those paid by municipalities, and 824 vaccinators; of the latter class there were six more than in the previous year.

This staff was responsible for a total of 1,147,820 operations as compared with 1,105,084 in 1898-99, and 1,258,010 in 1897-98, each vaccinator being credited with an average of 1,375 operations against 1,330 the year before. Although there is some decline on the total work of the year 1897-98, the results may be considered satisfactory, in that there is an increase in primary vaccination in local fund areas, and this is taken to indicate the subsidence of the plague inoculation scare which prejudicially affected the operations last year, and which doubtless has not entirely disappeared; there was, however, a decline in re-vaccinations.

Of the full total noted above, 1,086,602 were primary cases and 61,218 re-vaccinations, as compared with 1,028,221 and 76,863 respectively for the year before; and the percentage of success was higher, rising from 89·6 and 75·5 to 91·8 and 76·2, in the year under report. In addition to the above, the number of operations performed at dispensaries in 1899–1900 was 11,589 against 12,909, or 1,320 less than the year before.

Of this number 10,219 were primary cases and 1,370 re-vaccinations, and the percentage of success in the former rose from 83·6 in 1898–99 to 91·0, and in re-vaccinations from 68·1 to 71·5. With respect to the decline in Dispensary Vaccination, the Inspector of Vaccination and Deputy Sanitary Commissioner remarks:—"The number of cases in civil dispensaries shows a tendency to steadily decrease every year, and this is probably partly due to the increased energy exhibited by Local Fund and Municipal vaccinators."

Estimating the birth-rate at 40 per 1,000 of the census population, 22·74 per cent. of the infants were protected, as compared with 19·84 in 1898–99, and 22·81, the mean of the three years preceding.

The work of inspection received less attention than in the preceding year, the percentage verified to total operations falling from 3·0 and 56·7 by Civil Surgeons and Native Superintendents respectively to 2·8 and 51·6 per cent. during the year under report. The degree of success approved by Civil Surgeons fell to 82·1 per cent. from 86·0 per cent. the year before, but the results reported by Native Superintendents were better, viz., 88·1 per cent. successful as compared with 87·7 in 1898–99; vaccinators claimed 91·2 per cent. The Deputy Sanitary Commissioner apparently did no verification work. There was no new departure in the lymph used, which was of four kinds, viz., fresh calf lymph, animal lymph preserved in tubes or plates, glycerine paste, and lanoline paste.

The following exhibits the extent to which the several kinds of vaccine were used in the districts, excluding municipalities and dispensaries, as also the measure of success attending each.

—	Number of cases, primary operations and re-vaccinations.	Percentage of success.
Fresh Calf lymph	198,554	97·6
Ditto Preserved (without admixture) ...	102,902	95·8
Glycerine Paste	382,034	88·7
Lanoline „	348,213	88·5

In accordance with the experience of the past, the best results were secured with fresh calf lymph, and for the rest, as indicated in the order noted above. The results attained with lanolinated lymph in the previous year were slightly improved upon, and glycerine paste was far more successful than in 1898–99, when the ratio of success was only 82·4 per cent. It is notable that this last named preparation is now used as soon as possible after manufacture, the glycerine serving more as a diluent than as a preservative. The degree of success of glycerine paste would seem therefore to depend largely, in certain parts of India, on the time elapsing between the preparation of the paste and its use; the longer it is kept the greater the deterioration, so far as the experience of Madras tends to show.

Coorg.—During the year under review the constitution of the Vaccination Department was the same as in the preceding year, the staff consisting of one Native Inspector and eight Vaccinators under the supervision of the Civil Surgeon of the province. This staff performed a total of 9,996 operations, of which 8,091 were primary cases and 1,905 re-vaccinations, a satisfactory increase compared with the work of the previous year, when the total operations numbered only 5,283, and is attributed to the people having regained their confidence in the prophylactic which had been seriously shaken by the currency of a rumour that anti-plague inoculation was being practised in the guise of vaccination.

Of the primary operations performed 7,681 were successful, yielding a ratio of 94·93 per cent. against one of 93·15 per cent. the year before. Of the re-vaccinations 1,457 cases were successful, a percentage of 76·48 as compared with 80·93 in 1898-99. At dispensaries 481 operations were performed, as against 390 in the previous year; of these, primary cases numbered 309 and re-vaccinations 172, which proved successful at the rate of 75·40 and 55·23 per cent. respectively, against 72·80 and 60·93 in 1898–99.

The improved results of the year's work increased the number of infants protected from 7·38 to 11·70 per cent. of the births, estimated at 40 per 1,000 of the census population.

The inspection work of the Native Inspector shows an improvement, the percentage of his inspections to the operations performed having been 32·27 against 10·95 in 1898–99 and 31·93 in 1897–98. The Civil Surgeon's inspections fell from 7·95 to 2·25 per cent. The percentage of success found by these officers was higher than that claimed by vaccinators, viz., 90·35 per cent. Calf lymph was again exclusively used.

Bombay.—Excluding the Native States of the Presidency, the Department under the control of the Sanitary Commissioner, consisted of five Deputy Sanitary Commissioners and 45 Inspectors of Sanitation and Vaccination; while the operating staff comprised an average of 357 vaccinators.

The total number of operations performed was 769,267, of which 680,063 were primary cases and 89,204 re-vaccinations, which were successful at the rate of 92·60 and 41·62 per cent. respectively. This shows an increase of 98,823 on the total number performed in the preceding year, when the degree of success was 92·75 and 57·25 per cent. for the two classes of operations.

At dispensaries during the year, including those in Native States, 1,404 primary operations were performed and 2,257 re-vaccinations. This again is an improvement on the results of the preceding year, when the two classes numbered 998 and 917 respectively. The ratios of success were 88·95 and 88·83, as compared with 96·75 and 71·86 per cent. the year before.

The vaccination work carried out in the Native States consisted of 185,162 primary cases and 7,115 re-vaccinations, but these figures do not include the returns for the Palanpur State, for which the information was not received, as was the case in the previous year, and the returns are therefore comparable, and show a decrease of 7,733 primary cases and of 1,880 re-vaccinations as compared with 1898–99. The degree of success in the year under review was 95·76 and 70·04 for primary and re-vaccinations respectively, while in 1898–99 the results were 95·55 and 68·99 respectively. The majority of the operations were performed on infants and children under six years of age. The proportional protection afforded to the population of all ages was 27·01 per 1,000 against 28·23 in the previous year. The protection afforded to infants, calculating the birth-rate at 40 per 1,000 of the population, was 56·30 per cent., while in 1898–99 it was only 49·91 per cent., the mean for the three preceding years being 57·54.

The inspection work done by Deputy Sanitary Commissioners shows an improvement on that of the preceding year, having risen from 2·32 to 4·61 per cent. of the total number of operations, while the work of the Inspectors and Superintendents declined from 40·68 to 34·28 per cent. The percentage of success found by these two classes of officers was 90·65 and 96·92 respectively, against 85·83 claimed by the vaccinators themselves.

As in the previous year, inoculation was only practised in one place, which was, however, not the same, the offender, for the prosecution of whom steps were taken, plied his trade this year in the Kashmore Taluka of the Sind District. In addition to arm-to-arm vaccinations, it would appear that animal lymph was very largely used throughout the year, and in one place lanoline vaccine paste, obtained from the Bangalore animal vaccination depôt, was introduced.

Burma.—The Vaccination Department in Burma, under the control of the Sanitary Commissioner, was composed of the District Civil Surgeons, the Municipal Health Officers of Rangoon and Mandalay, 14 Native Inspectors (an increase of 2) and an average of 188 vaccinators (an increase of 11).

The total number of operations performed by this staff was 490,887 as compared with 466,308 in the preceding year and 421,786 in 1897–98. Both classes of work show an increase; primary cases rising from 439,050 to 456,762, and re-vaccinations from 27,258 to 34,125.

Re-vaccination has of recent years shown a steady rise, and it has been thought advisable to direct that more attention should be paid to the primary operation, as in the opinion of the Sanitary Commissioner, if this is efficiently performed, the need for re-vaccination is less urgent; nevertheless the work in the latter class is not comparable with the amount done in the small province of Berar.

The decree of success secured in primary cases was the same as in the year before, viz., 94·71 per cent., and in re-vaccinations 58·72 against 59·55 per cent.

During the year under review the Burma Vaccination Law Amendment Act was passed (Burma Act II of 1900), whereby the Superintendents of Vaccination in the Rangoon Municipality to which the Act may be subsequently extended, are empowered to require

unprotected persons to be vaccinated, and which provides for the compulsory vaccination of inmates of lodging-houses or coolie barracks. These powers should avail for the protection of the coolie immigrants in Rangoon, a class very liable to harbour and spread small-pox, the compulsory vaccination of whom was discontinued in August, 1896. It would appear that the Act did not come into force during the year under review, as the returns for the Rangoon Municipality are the lowest for the past 5 years, there having been only 2,457 primary operations against 16,083 in 1895–96, with 2,899 re-vaccinations against 7,568 in 1895–6. The discontinuance of the compulsory vaccination of adults is urged as the cause of the steady fall referred to, which, however, should now give place to a return to a better state of things under the new Act.

The rise in Dispensary Vaccination referred to last year was not maintained, there having been a total of 12,627 operations as compared with 14,349 in 1898–99. The decrease was, however, wholly represented by primary cases, these numbering 6,033 against 8,209 the previous year, while re-vaccinations showed an increase, 6,594, against 6,140. The percentage of success in these operations was 89·86 and 61·03, respectively, as compared with 88·66 and 62·70 in 1898–99.

As pointed out by the Local Government, the success in primary cases was considerably below the average for the whole province, while as regards re-vaccinations it was abnormally high. Many of the figures furnished are obviously incredible and impair confidence in the results as a whole, for, as it is noted, "in Magwe, 384 persons are reported to have been re-vaccinated, and all successfully, while in Sandoway, only four cases were successful out of 147."

Colonel Little remarks that "it is very evident that there is a considerable amount of false work returned by vaccinators . . . and an appreciable amount of incompetent and second rate work; this is clearly due to defective supervision and inspection, owing to the difficulty experienced by District Medical Officers in leaving head-quarters, and to the majority of the districts being without Native Superintendents."

The average number of operations performed by each vaccinator declined from 2,635 in 1898–99 to 2,611 in the year under review.

As in the preceding year, only primary vaccination was carried out in the Shan States; the figures, exclusive of the Dispensary Vaccination, were for the Northern States, 3,915 against 2,975, and for the Southern States, 4,347 against 3,750 in 1898–99. The degree of success, however, declined considerably, the percentage for the two States having been only 62·30 and 74·90, respectively, as compared with 82·49 and 86·80 per cent. in the preceding year.

Infant protection, taking the births at 40 per 1,000, is calculated to have been attained in 40·14 per cent. of the population under one year of age, as compared with 37·71 per cent. in 1898–99, and a mean of 29·4 for the three years preceding.

The inspection work of the Civil Surgeons shows an improvement, the percentage of cases verified to total operations having been 22·91 against 21·67 the year previous; on the other hand the work of the Native Superintendents shows a fall from 18·14 per cent. to 14·13 per cent. The staff of 14 Native Superintendents is considered inadequate, and the question of increasing the number is to be considered, but at the same time there appears to be no justification for the smaller display of energy than in previous years, especially in view of the quality of the work they have to supervise. Proposals for the reorganization of the entire establishment in order to secure better supervision, more general extension of vaccination, and a better quality of work, will be submitted to Government during the current year. The percentage of success found by the Civil Surgeons was 87·49, against 89·88 by the Superintendents, while vaccinators claimed 92·21 per cent. of their cases as successful. The corresponding ratios of success for the preceding year, were Civil Surgeons 89·35, and Native Superintendents 89·07 per cent., against the claim of 92·66 per cent. preferred by the vaccinators.

It is reported that the practice of inoculation prevails pretty generally throughout the province, and it is not surprising to find that the persons responsible and to whom it means a livelihood discredit vaccination, "as they spread small-pox from village to village." They have the sympathy of the people who are accustomed to the practice, and therefore, while appreciating vaccination, "prefer the old, though mischievous, usage, to what they regard as foreign inventions." Some of the native Burman officials exercise their influence to discredit vaccination.

The operations of the department were carried on by the use of humanized lymph through arm-to-arm transfer, and by glycerinated lymph prepared at the Rangoon and Taunggyi depôts. Some lanoline lymph was obtained from Bangalore and used in certain Municipal towns; no details are available as to the comparative results obtained.

It appears, however, that the lymph prepared at the Rangoon depôt was fairly successful, and met all reasonable requirements ; the quantity of vaccine prepared, as the result of the inoculation of 126 calves, was 27,390 grains, of which 26,971 grains were issued for use, as compared with 16,979 grains issued during the previous year.

The outturn of vaccine from the Taunggyi depôt was greatly in excess of that during either of the two preceding years, but the number of grains actually issued is not stated. In the early part of the year lanoline paste was prepared, but this preparation showed a tendency to become mouldy and to decompose readily, and so this vehicle was replaced by the use of glycerine, but even this was found to retain its potency only for a comparatively limited time. The results of the vaccine issued are conflicting, very good results being obtained in some places, while elsewhere it proved almost a complete failure. Various causes are assigned for this, but the Sanitary Commissioner considers a most important, if not the main, factor, to be probably the free use of perchloride of mercury both in the preparation of the calf and the collection of the vesicles. Difficulties in obtaining calves, &c., have decided the Sanitary Commissioner to propose the removal of the depôt to Meiktila, making it the source of supply for Upper Burma, while the Rangoon depôt will be available for Lower Burma.

Ajmer-Merwara.—In this small area of British territory in Rajputana, vaccination was as usual supervised by the Civil Surgeon of Ajmer. The staff comprised one Native Supervising officer and 13 vaccinators, being the same as in the two preceding years.

In 1899–1900 a total of 27,080 operations were performed, or an increase of 9,132 over the number for 1898–1899. Of the 26,077 primary operations, 25,838 were successful, a ratio of 99·08 per cent., and of the 1,003 re-vaccinations 911 were successful or 90·83 per cent. The percentage of success in the year 1898–1899 was 98·46 and 65·15 for the two classes respectively.

Calculated on an estimated birth-rate of 40 per 1,000 of population, the proportion of infants protected was 63·11 per cent. of the whole, compared with 55·34 per cent. in 1898–99, and a mean of 49·4 during the three years preceding.

Inspections by the Civil Surgeon were confined to the Ajmer district, where he examined 8·48 per cent. of all the operations performed therein, and found 98·91 per cent. successful ; the Native Superintendent verified 39·19 per cent. of the work, of which 98·70 per cent. was found successful.

Civil Sanitary Works.

Bengal.—There was no alteration in the number of municipal towns in Bengal during the year 1898-99 ; there are 151 excluding Calcutta, and their income during the year, including the opening balance of £26,731, amounted to £283,154, or £1,178 less than that of the previous year. Of the total income, 44·75 per cent. was spent on sanitary works (original and recurring), 9·97 per cent. on roads, 4·48 per cent. on measures for the preservation of public safety, and 29·32 per cent. on all other requirements ; these figures closely approximate to those of the previous year. The expenditure on water-supply was £13,426 against £17,511 in 1897-98, a decrease of £4,085, explained by a reduction in the capital and maintenance outlays on account of the Howrah and Bhagalpur works. Under conservancy there was a slight increase of expenditure amounting to £182, the total sum thus allotted being £70,768 during the year under review. Drainage works involved an expenditure of £7,785 against £7,564 in the previous year, but the cost of markets and slaughter houses showed a falling-off from £2,922 to £2,066 due to the decreased outlay by the Narayanganj and Darjeeling municipalities under this head.

The average proportion of municipal income applied to original sanitary works following the tendency of the last few years, was only 2·67 per cent. ; in the previous year it was 3·57 per cent., in 1896-97 it was 3·70, and in 1895-96, 5·03 per cent. Only 10 municipalities devoted over 10 per cent. of their income to this purpose, against 15 in the previous year, while 53, against 41 in 1897-98, spent nothing on this account. The tendency in recent years has been steadily backward and the Sanitary Commissioner expresses regret that such important *Sadr* towns as Faridpur, Comilla, Chittagong,

Chapra, Motihari, Muzaffarpur, Monghyr, Cuttack and Hazaribagh failed to carry out any original work whatever, and certainly a glance at Annual Form No. XI of the Provincial Sanitary Report is convincing in respect of the necessity of a more vigorous policy.

On the other hand the average expenditure under annually-recurring works, which was 41·73 in 1897-98, rose to 42·08 per cent., the proportions ranging from 65·98 per cent. in Berhampore to 8·93 per cent. in Chandpur.

The expenditure of public funds on rural sanitation amounted to £16,298 against £21,565 in the previous year, and £26,685 in 1896-97. Private individuals provided £20,328, which is a sum less by £12,060 than that of the previous year. That the total expenditure allotted to sanitary works in rural areas fell off by some 2½ lakhs in the year under review, if not satisfactory, was to be expected, owing to the diminished stimulus to the benevolent and wealthy which a generally prosperous year provides.

The official constitution of the Sanitary Board remained unchanged, though there were a few alterations in the *personnel* owing to official transfers and leave vacancies. Three meetings were held during the year, but consultative work was also carried on as heretofore by the circulation of papers to the members. The principal matters taken into consideration at the meetings were :—

(1) Model bye-laws for privies and urinals.
(2) The functions and powers of the Sanitary Board.

The more important preliminary estimates prepared under the orders of the Board were :—

(1) The scheme for the improvement of the Darjeeling water-supply. The Sanitary Engineer, after an enquiry into the present system, formulated a scheme estimated to cost £12,250, which has been adopted by the municipality.
(2) Patna water-works. The experiment, alluded to in last year's report, for obtaining a supply from a well sunk in the old bed of the river Sone having been successfully concluded, preliminary estimates for a series of wells to be sunk near the experimental well were drawn up and nearly completed at the close of the year.

Detailed estimates in connexion with the following works were prepared, viz :— Two alternative schemes for filter beds for the purification of the water-supply of Patuakhali ; one was approved and sanctioned by Government.

The plans and estimates which were noted in last year's report for the flushing of drains in Ward No. 5 of the Patna Municipality and for the Berhampore water-works having been approved, the works were completed during the past year and are reported to be most successful.

Estimates and plans for the following projects were considered :—

(1) Improvement of the drainage of Manicktolla. This scheme, which had to be returned for re-submission, was partially approved, certain modifications being proposed.
(2) Drainage of the Siwan Municipality. This project having been revised according to the suggestions of the Sanitary Engineer was approved by the Board, and recommended to the Government for sanction.
(3) Re-modelling of the intake of the Dacca water-works. Owing to the silting up of the channels from which the water is taken, it was proposed to ascertain whether a sufficient supply could be obtained from wells sunk in the *chur*. The Executive Engineer was authorised to conduct the necessary boring experiments.
(4) Dinajpur drainage scheme.
(5) Drainage project for Chattra and the western portion of Serampore. Instructions were issued to the local authorities to revise the scheme.
(6) The intake of the Bhagalpur water-works. Owing to the choking of the intake with sand, a proposal has been made by the Board that the most satisfactory solution of the difficulty lies in the sinking of a system of wells, and the Chairman of the Municipality has been so advised.
(7) Drainage scheme for the Challam bheel in Rajshahi.

During the year drainage surveys of Khulna and a part of Serampore were completed, and that of the Rishra bustee in Serampore was in progress. Miscellaneous references were made to the Board by Government and by local authorities, notably in connexion with the drainage projects of the Natore and Bihar Municipalities.

The sewage disposal experiments referred to in last year's report were carried on, but no definite report of the results has been presented, owing to the Sanitary Engineer's desire to submit the system for a whole year "to the several tests in the matter of the concentration of the sewage dealt with." It is understood, however, that the experiments have so far been successful.

The Sanitary Engineer made numerous inspections of towns in connexion with various sanitary works and schemes, and the Board tenders its acknowledgments of his "active and efficient service."

Assam.—The total income of municipalities and all local bodies during the year was £18,395, as compared with £17,326 in the previous year; and of the total 42·74 per cent. was spent on sanitary works proper, as compared with 45·52 per cent. in 1898.

Shillong station comes first with an expenditure of 79·37 per cent. of income, followed by percentages in Gauhati of 77·98, and in Dibrugarh of 72·23, down to the Barpeta municipality with 38·23. No work of capital importance was undertaken, but the money is said to have been well spent on the various objects of vaccination, drainage, market places, improvements to water-supply and general conservancy. The Gauhati municipality spent a considerable sum in the repair of existing drains, and £976 went to the improvement of the water-works and the purchase of a new pontoon and pulsometer. In Shillong station the old latrines have been cleared away and replaced by new pattern iron structures, and while something has been done to repair the damage done to the water-works by the earthquake of 1897, it would appear that funds are needed to complete the works. The water-supply of Sylhet has been improved and largely increased by the sinking of a new well.

In rural areas the chief sanitary measures undertaken have had reference to the water-supplies, the excavating and cleaning of tanks and the sinking and repairing of wells.

The use of the village sanitary inspection books has not improved during the year; some districts have neglected the orders on the subject altogether, and in the majority, where the letter of the rules is carried out to a greater or lesser extent, the practical benefit has so far been insignificant or altogether wanting.

The Sanitary Board held no formal meetings during the year, but the opinions of the members were obtained on all sanitary matters of importance by the circulation of papers. The Government of India having invited attention to this matter in their review of the report for 1898, meetings of the Board "have since taken place and will be continued in future."

North-Western Provinces and Oudh.—The number of municipal towns remained the same, 104, as in the previous year. Excluding opening balances, the total municipal income was £318,355, compared with £298,878 in the previous year, and the total expenditure on sanitary works amounted to £110,590, or 35 per cent. of the former sum. The expenditure on water-supply was £36,196, a slight increase on that of 1897-98; on drainage it was £7,754 against £12,073 in the previous year, and on conservancy it was £64,751 against £66,009; the sum allotted to markets and slaughter houses was £1,889, practically the same as the previous year.

The more important sanitary works undertaken during the year included no new departure, but took the form of the development of schemes already commenced; these were, notably, considerable extensions of the new sewerage works at Benares and extensions of the Naini Tal and Cawnpore water-works. Although only nine of the municipal towns have been furnished with a pipe water-supply, it is pointed out that nearly one-third of the entire municipal population of the province now enjoys this advantage. There is abundant evidence that every care was devoted to all the details of management, and to the improvement, where necessary, of the various works.

At Agra, the average daily consumption per head fell slightly, from 8·96 gallons to 8·61; in the cantonment also a decrease of consumption was registered, viz., from a daily average of 164,013 gallons in 1897-98 to 156,679 gallons in the year under report. The cost per thousand gallons of filtered water, which was 1·59 annas in the previous year, rose to 1·65 annas, but a large expenditure was incurred in special repairs to engines and pumps.

At Allahabad, owing to the early cessation of the rains; the average daily consumption of filtered water rose from 1,410,229 to 1,490,803 gallons, equal to 8·5 gallons per head of the population, and this was distributed at a cost of 1·61 annas per 1,000 gallons, a trifling increase over that of the previous year. Observations having shown that a loss of 90,000 gallons a day was taking place from one of the filter beds, closer investigation proved that the floor was badly cracked and this was successfully repaired.

At Benares the consumption of filtered water has shown an extraordinary increase, as the following figures demonstrate :—

	Gallons.
1897-98	695,404,100
1898-99	852,670,719
1899-1900	960,202,743

Thus, within three years, the consumption has risen nearly 40 per cent., although the house connexions have only increased 12 per cent. The quantity per head represented by the figure for the past year is 12·2 gallons, largely in excess of that of any other municipality in the province ; there is evidence of large wastage due to defective pipes, taps and fittings, and to misuse of the water for house-drain flushing. The cost per 1,000 gallons was only 1·01 annas.

In Cawnpore the daily average consumption of filtered water was 9·17 gallons as compared with 8·74 in the previous year, the cost per thousand gallons being 2·05 annas. A steady increase in revenue from the sale of water is noteworthy, but the city is exceptionally situated in this respect.

At Lucknow the average daily consumption in the city and cantonment was 1,071,498 gallons, equal to 5·4 gallons per head of the population within reach of the supply ; the cost per thousand gallons was 2·06 annas. In addition to this filtered water, 64½ million gallons of unfiltered water were supplied to the Parks during the year.

In Meerut there has been a gradual decrease in the consumption during the last three years, *viz.*, from a daily average of 461,899 gallons in 1897-98, and 406,235 in 1898-99 to 336,008 in the past year ; this decrease is the subject of enquiry.

At Naini Tul the daily supply of water was over 11 gallons per head of population. I have already noted that the remodelling and extension of the system was completed during the year, and pure drinking water is now delivered within a short distance of every house in the settlement, besides being extended to the cantonment. The total expenditure on the works to the end of the year amounted to £14,615 against a sanctioned estimate of £17,000 ; and there will ultimately be a saving of over £1,600.

During the year samples of the various filtered supplies were regularly analysed, chemically and bacteriologically, "and were almost invariably found free from suspicion." In September it is said that "enteric microbes were detected in the Agra Cantonment water, but the mischief was checked before any evil effects resulted."

The new sewerage works at Benares made fair progress, and an expenditure of £4,850 was incurred thereon during the year.

The question of the disposal of the Cawnpore sewage was fully considered. Various proposals have been put forward, including schemes by English Sanitary Engineers, and the whole subject has lately been carefully considered by the local sanitary and engineering authorities whose joint note is now under discussion by the Municipal Board.

Surveys and estimates in connection with the following towns were carried out and prepared : Aligarh, Hathras, Saharanpur, Pilibhit and Sitapur.

The Sanitary Board held four meeting during the recess : three at Naini Tal and one at Agra, and the following were among the more important matters that engaged their attention :—

(1) The report by the Sanitary Engineer on the quality of the municipal water-supplies. It was noted that the "quality of the water was quite satisfactory," except in the case of Agra where it was deemed necessary to take further precautions to prevent contamination of the river near and above the intake and to provide additional filter area. Designs and estimates to this end were prepared and approved.

(2) Certain objections raised by the military authorities to the condition of the river banks above the intake of the Benares water-supply were considered, and the fact that the very numerous chemical and bacteriological tests carried out during the last two years showed an exceptional standard of purity, was held to be strong evidence that danger was more hypothetical than real. It was, however, recognised that additional safeguards should be employed to purify sullage water discharging into the river.

(3) The water supply of Jhansi. It was decided that alternative schemes for obtaining a supply from wells and from the Pahuj river should be fully considered.

(4) Various questions raised by the Sanitary Commissioner regarding details in connection with the Benares sewage works were referred to the Board for consideration, and recommendations made thereon.

(5) A note by the Sanitary Engineer on the question of a drainage scheme for the town of Deoband was discussed, and the Board recommended that the Irrigation Department should prepare a complete scheme for the drainage of the area surrounding the town, as a preliminary measure, as otherwise no efficient outfall for the town drainage is practicable.

Punjab.—The total income of the 31 municipal towns, including the opening balance, was £385,271, as compared with £368,806 in 1898; there was a corresponding increase of expenditure on sanitation which amounted in the aggregate to £93,446 against £75,007 in the previous year. The increase is fairly distributed over all the more important heads of sanitary work; drainage and sewerage, however, coming first with nearly one lakh in advance of the outlay in 1898, while the cost under conservancy establishment shows an excess of about half a lakh, and water-supply one quarter of a lakh. The sum realized from the sale of manure in all municipal towns amounted to £9,521, as compared with £9,900 in 1898 and £9,942 in 1897; the question of this decrease is the subject of enquiry.

The principal sanitary works completed, in progress, or under consideration during the year, were the following:—

The excavation of the settling tanks and filter beds of the Delhi water-works was completed and the masonry work commenced. The huge Seog reservoir (near Simla) and the whole of the work on the weirs, screening tanks, filter-beds and pipe laying of the gravitation supply to the pumping station at Cherát, in connection with the Simla water-works extension, was completed. Beyond this, additions and alterations to some of the filter-beds were carried out, along with some minor works in connection with the distribution system. Survey work for the new project for the extension of the sewage system is in active progress. Various schemes for the drainage of certain cities and towns are in different stages of initiation or progress, but the only work of this kind actually completed was in Ladwa; the important Chandni Chauk section of the Delhi drainage works was held in abeyance for want of funds, and the Umballa city drainage scheme awaits sanction. Various sanitary works of public utility were constructed by private individuals at their own expense during 1898–99—wells, tanks, rest-houses. The aggregate amount expended in this way by private charity being £5,162.

There is evidence that the important question of rural sanitation is engaging the earnest attention of the authorities. The village sanitary note-books are having a fair trial in most of the districts, and the endeavour to stimulate the interest of the people themselves in the cause of sanitation by the offer of monetary rewards to the village in each tahsil which shows most improvement in its sanitary condition, is still in the experimental stage.

There were seven meetings of the Sanitary Board during the year. The question of extending the scope of the Board's powers and functions is still under consideration, and certainly in the record of the proceedings for the year there is evidence that its energies and abilities are not suitably employed, and in this respect the contrast with the work and usefulness of the Boards in the North-Western Provinces and Bengal is marked.

Central Provinces.—The income of the 18 *Sadar* towns which was £95,467 in 1897–98 fell to £67,263 in 1898–99, a remarkable decrease which is not explained, but the total expenditure on sanitation rose from £20,882 to £27,159. The most notable increase under any one head is in the expenditure on water works; in the former year the sum so allotted was £5,275 against £13,092 in the latter. The cost of conservancy on the other hand fell off from £13,992 to £12,294.

The "Fraser" water-works at Wardha were completed and opened for use in November 1898, the total cost amounting to £15,027. The Bhandara water-works, begun in February 1898, were approaching completion at the end of 1899, and have since been opened.

The Harda scheme is still held in abeyance owing to a difficulty about funds, but a temporary project has been prepared to which a sum of £1,334 has been allotted by the Municipal Committee.

The drainage of the city of Jubbulpore has been started on a systematic plan, but it is noted that progress must be slow until the loans raised for the water-works have been paid off. A good deal of useful work was carried out in the way of laying down *pucka* drains in the lanes and alleys of the worst part of the town, and linking these up to the

street drains. Considerable progress has been made on the outfall drain, and facilities are being offered to owners of adjacent land to utilise the sewage thereon ; the result on the crops already raised is reported as favourable.

The provisions of the Village Sanitation Act have now been extended to 40 villages in all, but the Sanitary Commissioner notes of seven districts that the Act is either not in force, or was not enforced during the year. The total expenditure on village sanitation amounted to £4,099 out of a total allotment of £8,793. Of the sum spent, £1,923 went to the construction of wells, and £666 to repairs of wells ; £770 were devoted to the cleaning of village sites, and over £100 were expended on roads and drains. Wardha district stands first with a total expenditure of £1,050, followed by Bilaspur with £533, and Chanda with £400 ; six districts spent less than £67, and one district, Damoh, spent nothing at all on village sanitation.

The work of preparing sanitary maps, forming sanitary circles and drawing up village lists had been so far completed in 1898 that it was proposed to commence the registration of vital statistics on the basis of the new sanitary units, on January 1st, 1899. But in view of the presence and the danger of the spread of plague, together with the lack of funds, it was decided to postpone the new departure, and another year or two will probably elapse owing to the recurrence of famine, before it can be introduced with a fair chance of success. The presence of famine has also militated against progress generally, as much routine inspection work by civil surgeons had to be suspended in favour of more pressing duties.

The Sanitary Board for the same reason held only one meeting during the year. The principal business was the discussion of the proposals and estimates for works of sanitary improvement in villages.

Berar.—The estimated income of the 12 municipal towns in Berar in 1899 was £18,116, against £17,702 in 1898 ; the actual expenditure on sanitation was £8,776 as compared with £8,984 in the former year. The percentage for the province is therefore 48·5, and ranges from 72·6 by Shegaon to 29·2 by Akot. The aggregate expenditure on water supply was £2,416, against £2,898 in 1898 ; on conservancy £4,767, against £4,209 ; on drainage £158, against £196 ; and on miscellaneous works £1,437, against £1,682 in the previous year.

Karinja has invested £1,334 for its drainage scheme, which will be put in hand after a proper survey has been carried out by the Public Works Department. Plans are being drawn up for a drainage scheme for the Ellichpur Municipality.

The outlay on water supply represents the repayment of loans, the Public Works maintenance charges for tanks and pumping charges. The deficient rainfall of the past two years has made the water supply question a critical one owing to the drying up of tanks, and the Sanitary Commissioner urges the provision by municipal bodies of a two or three years' supply, to be obtained by the enlargement of the tanks by famine labour. Something was, however, done in each district outside municipal limits to increase and improve the scanty supplies by deepening tanks, sinking new wells, and in cleaning and repairing old wells. Out of a total expenditure of £4,196 on these measures the Akola and Amraoti District Boards spent over £2,700.

The total sum expended by District Boards on sanitary works outside municipal towns was £7,954, against £5,170 in the previous year ; included in the former sum there was an increase of £496 under drainage, and of £2,252 under water supply.

At most of the towns night soil is trenched, and the ground is cropped "wherever feasible." But in some places night soil is still buried in pits and subsequently sold to cultivators, and the Sanitary Commissioner hopes soon to be able to report that the latter method of disposal has given place to the former in every municipal town.

A large amount of work devolved upon the medical and sanitary executive in the supervision and sanitary control of famine relief works, and it was only to be expected that under the circumstances the cause of village sanitation should receive less attention than usual.

No information is given by the Sanitary Commissioner about the proceedings of the Sanitary Board, an omission that was noted last year, but to which attention has been drawn in the review of the report for 1899.

Madras.—Excluding the Presidency town, the estimated income of the 60 municipal towns in Madras for the year 1899-1900 was £233,208, as compared with £197,082 in the previous year. Although a sum amounting to £129,574 was allotted for sanitary purposes, the aggregate actual expenditure during the nine months ending December,

1899, was £60,906, against £56,330 in the corresponding period of the previous year. The relative distribution of these sums in the two years may be seen at a glance in the subjoined statement, which also gives the figures for the city of Madras for comparison.

Heads of Expenditure.	Sixty Towns. Population=1,687,563.		Madras City. Population=436,375.	
	1898.	1899.	1898.	1899.
	£	£	£	£
Conservancy	33,212	32,652	19,734	22,600
Improvement of village sites	10,136	11,633	3,530	4,618
Improvement of water-supply	8,021	13,082	887	2,818
Sanitation of fairs	499	504	7	—
Markets and slaughter houses	550	969	1,900	5,022
Other miscellaneous sanitary works	3,912	2,066	9,908	4,656
Total	56,330	60,906	35,966	39,714
Income	197,082	233,208	89,877	96,477

The Sanitary Commissioner points out that no public body could foresee whether its ordinary resources or its borrowing powers would not be strained to the utmost by being called upon for extraordinary expenditure on account of plague measures, and hence the policy pursued was to keep a considerable balance in hand; consequently no sanitary work of great importance was initiated during the year. The water-supply system of Tirupati was completed in time for the great annual Hindu festival held there, and the extensions to the water-supply systems in Tanjore and Conjeeveram were also completed. But beyond this, important works are in the stage of consideration or suspension. For example, schemes were under the consideration of the Sanitary Board for the improvement of the water-supply of Tuticorin, for the extension of the Trichinopoly water-works, and for water supplies to Guntur, Periyakulam and Bezwada, and these were laid before Government. Preliminary proposals were also considered for the water-supply of Vizianagram, Cuddalore, Ellore, Negapatam and Saidapet, for the improvement of the water-supplies of Ootacamund and Cuddapah and for the drainage of Kumbakonam, Madura and Cuddapah. The following projects received Government sanction, viz., for the extension and improvement of the water-supplies of Trichinopoly and Tuticorin, for the water-supply of Coonoor, and for the drainage of the Tanjore Fort. In the less ambitious but very important sphere of conservancy in municipalities, the evidence adduced goes to show that very considerable progress has been made during the past four years, and the efforts of the Sanitary Commissioner to "substitute quality for quantity" in the matter of the supervising staff, by the employment of certificated Sanitary Inspectors in the place of the uneducated overseer and maistry, have been amply justified by the results. The amount realised by the sale of night-soil and rubbish was £2,130, but the ryot who originally looked askance at inodorous poudrette is gradually losing his prejudices in face of the excellent results of the raw article on his crops, and the price of night-soil shows a steady advance. Trenching, followed by cropping, under municipal auspices, was conducted as an object lesson at Bellary, Erode, Anakapalle and Nagore. At Karur, Rajahmundry, Tinnevelly and Negapatam sewage farming was conducted with profit, and at Kumbakonam, Bezwada, Vizagapatam and Vizianagram "biological" purification (intermittent downward filtration) was employed to protect streams to which the sewage would naturally gravitate, from gross pollution. At Guntur and Vizagapatam arrangements are in progress for sewage farming to be started next year.

The estimated income of the District Boards in 1898-99 was £574,323, and the allotment for sanitary purposes was 7·2 per cent. against 8·3 in the previous year; this ratio implies an allotment per head of population of 3·6 pies. During the nine months, period ending December, 1899, £25,796 were spent (against £24,656 in the corresponding period of the previous year), and this included the sum of £17,260 on conservancy and £3,372 on water-supplies. The falling-off noticeable in outlay during the past two years

is attributed to the necessity for keeping funds in hand for the possible call for expenditure on plague measures, but also to the questionable "economy" of district boards in discharging "sweepers" who would not remove night-soil, but whose places should have been taken by scavengers proper. Although the fear of plague has been the beginning of wisdom as regards sanitary effort in some places, in others it is to be feared that the cause has suffered owing to the "economy" practised to maintain an available fund for the emergency. The Sanitary Commissioner criticises the system of the formation of the union for practical sanitary effort, his main objection being that the available funds are dissipated in small useless measures such as lighting in the richer neighbourhoods, whereas district boards should concentrate their resources on definite works of a permanently useful kind in selected villages where the need is most crying. Another useful feature of his report is the critical discussion of the results on the public health of the schemes of water-supply and drainage already carried out.

The constitution of the Sanitary Board remained unchanged, but the rules for the conduct of business were modified to permit a local board or municipal authority to apply to Government for orders when it objects for financial or other reasons to adopt a design or estimate prescribed by the Sanitary Board. The Board scrutinised plans and estimates for one provincial, 34 municipal, and 79 local fund works of the estimated aggregate cost of £128,875. Six new standard type designs of minor sanitary works were approved for issue, the Board keeping in view the necessity for the less expensive designs suitable to the moderate resources of the minor local bodies.

Coorg.—A sum amounting to £432 was expended in this small province during the year 1899, of which £319 were expended in the erection of the D'Souza European ward and nurses' quarters at the Mercara hospital, the balance being chiefly devoted to conservancy and to repairs of existing water-supplies.

The Sanitary Board held three meetings during the year, at which plague regulations were discussed and approved, and various other practical matters connected with the apprehended outbreak and spread of the disease were settled.

In order to enhance the value of the village sanitary inspection books the civil surgeon has drawn up a series of simple and practical questions to be answered by the village head-men, which will, it is hoped, serve to direct attention of this official to the chief points of his duty, and maintain a useful record of actual work accomplished.

Bombay.—The number of municipalities in the Presidency in 1899 was 166, excluding Bombay City; these contain an aggregate population of 2,200,455 souls, the total income for 1898-99 being £368,466, or £13,366 in excess of that of the previous year. Of this sum £182,924, or nearly 50 per cent., were allotted for sanitary works, and 85·16 per cent. of the allotment (£155,778) was spent. The chief items of expenditure were £67,000 on conservancy, £31,103 on water-supply, £9,398 on town sites improvements, £4,172 on markets and slaughter-houses, £2,438 on the sanitation of fairs, and £41,669 on miscellaneous minor sanitary projects, *e.g.*, construction and repair of tanks, &c. These sums are approximately equal to those spent on the various objects in the previous year, except in the case of water-supply, on which the expenditure incurred was about £3,400 less than in 1897-98.

The Sanitary Board prefaces its report once more with the statement that, owing to the heavy expenditure incurred in the campaign against plague, the financial pressure upon municipalities has caused the deferment of many important sanitary projects. During the past year famine has involved a further claim on municipal finances, and in default of Government aid the prospects of sanitary work in the near future are very unpromising.

At Hyderabad municipal "dissensions" have caused delay in the erection of the new engines and in the construction of the engine-house for the river pumping station. The plans and estimates for the final completion of the water-works are still under the consideration of Government.

At Ahmedabad the drainage-scheme prepared by Mr. Baldwin Latham is still under discussion, and little progress is anticipated until a special engineer is put in charge of the work, as the local Executive Engineer has his hands full of other pressing matters.

At Kaira and Mehmadabad and Yeola the situation has not advanced from the position indicated in last year's report.

At Ahmednagar the completion of the Kapurwadi tank is now being carried out as a famine relief work; the distribution scheme in connexion therewith will shortly be forwarded to Government, but unless a loan is forthcoming there is no near prospect of practical results.

At Poona the drainage-scheme has been approved by the municipality, by Government, and by Mr. Santo Crimp, who was called in to advise. The original project to treat the sewage on the septic tank system has been modified in detail, but not altered in principle. In place of septic tanks and filters, it is now proposed to pass the sewage first through shallow upward filtration beds (the so-called "macerating tanks" in use at Wimbledon) and then to dispose of the effluent therefrom upon arable land for farming. This excludes the alternative plan of turning the effluent into the river, and as experiments have demonstrated the value of the effluent as food for crops, a large saving on the expenditure is looked for from the return on the farming operations.

A water-supply scheme for the city is also under preparation, and it is hoped the project will be ready for discussion by June 1900, but here again much depends on Government assistance, if the practical results are to be realized at a comparatively early date. The Sanitary Board adds "regarding the other towns and projects no progress has been made, and each year only enforces the urgency of the representation made last year to Government, to the effect that the Board should be granted executive and not merely consultative powers; and this especially in times like the present when every Executive Engineer is over-worked owing to the operations of famine relief."

In addition to the above, the Board advised on several minor projects, *e.g.*, the water-supply to the Central Jail at Hyderabad, on the Ahmedabad Sewage Farm, etc.

The district boards as a whole appear to have recovered from the financial depression of the last two years; their aggregate estimated income rose from £256,146 in 1897-98 to £381,833, but of this sum £38,627 were allotted to sanitary works, or only some 10 per cent. as against 18 per cent. in the previous year. The actual expenditure was, however, only £22,814 against £32,164 in 1897-98, and of this sum 72·44 per cent. (£16,530) was actually spent on improvements to water-supplies.

The Village Sanitation Act was introduced into five more villages during the year, but abolished in four villages, an increase of one, making the number 330 in all, in which the provisions of the measure operate. The village sanitary inspection books are in use in 3,225 villages against 3,199 in the previous year; it is, however, again noted that the presence of cholera and famine have interfered with the full utilization of these records.

The number of meetings held by the Sanitary Board is not stated, but the members are, apparently, in continuous communication with each other, and much useful work was done during the year, to the most important of which allusion has been made above.

Burma.—The total income of the towns and districts in Upper and Lower Burma in 1899 was £565,544, or £113,778 more than that of the previous year; the aggregate expenditure under all heads for sanitary purposes was £151,070 or £3,043 less than in 1898. This amount includes a sum of £55,846 for "other sanitary works," some of which have a very indirect bearing on sanitation. The amount devoted to water-supply was £55,746 against £26,056 in 1898; on drainage £27,770 against £27,255, and on conservancy, £43,661 against £40,508. The percentage of income spent by municipalities on sanitary works was on the average 34, but varied irregularly through a wide range, the only consistent item being conservancy and "other sanitary works." Only 13 of the 40 municipalities spent anything on water-supply, and of these 13, Rangoon and Prome, spent only 8 and 7 per cent. respectively, the other 11 being credited with insignificant sums. Again, only about half the number of these towns spent anything on drainage, and neither in this respect nor in that of water-supply was any work of importance undertaken. In 27 towns the expenditure on conservancy was less than 20 per cent.; in Kyaukpyu and Mandalay, by an obvious error, nothing is shown under this head, and a perusal of the reports of the Health Officers affords striking evidence that much remains to be done in the way of simple sanitary reform.

The Rangoon water-supply which has long been a reproach to the responsible local authorities, is now receiving the attention it deserves; the present supply from the lakes has been definitely proved to be liable to gross pollution, and the solution of the problem appears to lie in the direction of the resort to tube wells and the filtration of the water from selected lakes, the drainage area of which will be more scrupulously conserved.

The scheme for the Moulmein water-supply has also exercised the responsible local authorities, and the report of a committee of Engineers appointed to report on Mr. Foy's plans has been received and considered by the municipality, and it has been decided that the work should be carried out as a contribution work by the Public Works Department.

The preliminary survey of the Kanthonzin water-supply scheme for Bassein was completed, and as the Sanitary Commissioner remarks that this town badly needs a good water-supply, it is to be hoped that the difficulty in the provision of the necessary funds (estimated at

about £27,000) which the Municipal Committee declare they are unable to meet without help from Government, will not compel a resort to the dangerous alternative of a resort to open surface tanks.

The Mandalay water-supply is obtained from deep and shallow wells, only a "few" of which are reported by the Health Officer as "pure and wholesome." It is said that a "few have been remedied during the year, and there is much more to do," but funds are wanting. Mandalay spent nothing on water-supply, and only 1 per cent. of its income on all sanitary works.

A scheme for the improvement of the open surface drainage of Rangoon is under consideration, which should include the prevention of the abuse of these channels by a stringent reform of the conservancy arrangements and the prosecution of offenders. The attempt to obtain a survey of Moulmein for the improvement of the drainage has been frustrated by the departure of the surveyor and the incompetence of his successor. A scheme for the improvement of the Prome drainage has received the approval of the Sanitary Engineer, and is now in hand; this involves the construction of a total length of 20 miles of channels, of which two have been completed. The general scheme for the drainage of Bassein awaits a solution of the water-supply question already alluded to.

Village sanitation is receiving more attention, but progress, as is to be expected in Burma, is slow; it is something to have a definite assurance that the necessity of conserving the water-supplies is being more widely recognized by the people, but it is noted that the district medical officers have not in all instances given so much attention to this part of their duties as could be wished.

No meetings of the Sanitary Board were held during the year owing chiefly to official changes and departures. Proposals for the resuscitation of the Board and for some alterations in the procedure for the disposal of work are under consideration, and will shortly be submitted to Government.

General Remarks.

The investigation of Indian fevers.—The brilliant researches of Major Ronald Ross which were summarised in this report for 1897, and the confirmation they have received at the hands of Koch and the Italian school, and not least of the new English schools, have had a marked influence in inciting recent workers in India to the pursuit of observations in the new field of parasitology thus opened up.

As one important result we may cite the work of Captain S. P. James, I.M.S., independently confirming the observations of Manson, Bancroft and Low, that mosquitoes of the genus Anopheles are capable of acting as efficient intermediary hosts of the parasite of "Filariasis" (*Filaria Sanguinis Hominis*); and as regards the practical point of the mode of infection, his dissections of the head tissues of the *Anopheles Rossii*, after the *filaria* had undergone its metamorphosis during a period of 12 to 14 days, leave little doubt that (in the words of Bancroft) "young filariæ may gain entrance to the human host whilst mosquistoes bearing them are in the act of biting." On the question of the rôle of the mosquisto in the propagation of malarial fevers a considerable and increasing number of medical officers are devoting themselves to the marking down of the breeding-places of the definitive host, supplemented by the clinical use of the microscope, and it is to be hoped that systematic observations sustained throughout the different seasonal periods of the year and in varying climatological and geographical areas, will afford valuable evidence, which will either serve to confirm or to suggest the inadequacy of the latest theory to explain all the established facts of the natural history of the disease.

Just as the remarkable discovery of James and Low of the living filaria in the probosces of different genera of mosquitoes, although suggestive of one means of infection, cannot be accepted as excluding the possibility of a water-borne infection, so also must we hold with Manson,* with regard to malarial infection, by direct inoculation by the bite of mosquitoes, "that this is the complete story is by no means sure." Referring to places which are practically uninhabitable on account of malaria, "and where there are few human inhabitants, if any," he asks pertinently, "if man be a necessary factor in the malaria cycle, how are we to account for malaria in such districts?" To this he replies

---

* (Volume VIII, Allbutt's System of Medicine, Appendix of Malaria.)

that it is possible that, in such places, some other vertebrate may take the place of man, or it may be that the intervention of a vertebrate is not indispensable, the malarial parasite passing direct from one generation of mosquitoes to another, just as the sporozoal parasite of Texas fever is transmitted from the parent to its offspring. In connection with outbreaks of malaria associated with the excavation of the soil in engineering works, he finds it difficult to explain how mosquito activity can be specially affected by the turning over of a few feet of earth, and he recalls Ross' observations on the highly resistant "black spores," and suggests that these may represent a "resting" stage of the parasite, which may remain dormant in some, as yet, unascertained medium for an indefinite time until the unknown appropriate conditions arrive for their re-entry into the pathogenic life-cycle.

Smith, so well known in connection with the study of Texas fever, holds a similar view of the possibility of an alternative mode of infection. During the short time that has elapsed since these suggestions were published, the labours of the large number of investigators now in the field have gone far to modify them; and to one or two points, notably the direct transfer of the parasite from one generation of the mosquito to another, tho results of recent research are altogether opposed; it may be said that the direct inoculation theory holds the field, and that the *onus probandi* of an alternative mode of infection rests upon those who would take exception to the former view.

Every honest observation must be welcomed than can be urged and duly substantiated on the one side or the other of the question, the solution of which will indicate practical methods of prevention, and it is on this account that an enquiry recently made by Captain Rogers I.M.S., into the conditions obtaining in a notoriously malarious locality on the bank of the Hooghly, near Calcutta, have a suggestive interest; that is to say when we bear in mind the close analogy that obtains throughout the life-histories of the parasites of malaria and filariasis, and take into account the evidence which connects the latter disease with the drinking of infected water.

For if the evidence of the conveyance of infection by drinking-water should ultimately be disproved, we cannot surrender the established facts of the influence of the environment, of which the drinking-water is a prime factor, upon the prediposition of the human organism to disease. The removal of this predisposition is the fundamental principle of the prevention of all infectious disease, and as has been well said by a philosophical hygienist, "where the danger of fire is great, the extinction of myriads of individual sparks will always be less valuable service to the community than the intelligent construction of the house and the adaptation thereof to existing conditions."

The question Captain Rogers set himself to determine was the proportion of persons, in different parts of the area, who were at the time suffering from the effects of malaria as indicated by the enlargement of the spleen, and to this end, between five and six thousand persons of all classes and ages were examined. In addition the water level was measured in as many wells as could be found, and enquiries were made as to the height to which the water rises in these wells during the rains. The main drainage channels of the area were examined; the drinking-water supplies of the different communities were enquired into and carefully noted; and, lastly, returns of the number of cases of fever treated each month of the year in most of the public dispensaries were obtained, and compared by means of charts with the monthly rainfall of recent years, with the object of ascertaining if there be any definite and constant relationship between the amount and distribution of the rainfall and the prevalence of malarial fevers. It is unnecessary here to follow Captain Rogers in the account he gives of the precautions taken to secure a fair average approximation to the relative prevalence of enlargement of the spleen among the inhabitants of the different towns and villages included in the arear surveyed. He gives a suggestive table contrasting the "spleen percentages" in the municipalities located in two areas, running roughly parallel from north to south, one being situated on the east bank of the Hooghly river and the other still further to the east, at distances varying from two to twenty-six miles from the former. The spleen percentages in Group I ranged from 11·2 (in Cossipore-Chitpur) to 37·8 in Titagarh, with an average for nine municipalities of 24·5. Whereas in Group II the percentages varied, with one exception, from 32·3 in south Dum-Dum to 68·1 in north Dum-Dum, with an average for eight municipalities of 41·0.

The one exception referred to in the latter group was Maniktala, only 13·2 per cent. of the inhabitants of which were found to suffer from enlarged spleen, a rate comparable with that of Cossipore-Chitpur in Group I. It may be added that the average death-rate from "fevers" recorded in the Sanitary Commissioner's reports bears a close relationship,

as regards the relative incidence, to the "spleen rate." The average "fever" death-rate for the last five years in Group I is 21·3, that for Cossipore only 9·1; while in Group II., excluding Maniktala, it is 23·3, and for the last-named place only 8·2.

It would therefore appear that, by comparison, the towns situated immediately on the east bank of the Hooghly are relatively healthy, and that directly we pass into the lower lying tract to the east we encounter strong evidence of conditions that give rise to intense malarial infection, but with the one notable exception named. Maniktala, situated on extremely low-lying and water-logged land, has nevertheless a spleen rate, and a fever death-rate, approximating to the lowest in the healthier area. Captain Rogers then proceeds to an analysis of the various local conditions under which these communities live, and concludes that the lowest spleen rates are invariably associated with one common factor, viz., a good filtered water-supply. At the same time he is careful to allow that position in regard to water-logging is a factor to be taken into account. A closer analysis of the spleen rate in different wards of the same municipality lends support to this view, and helps to explain apparent divergencies from the rule in certain localities which are only partially supplied by the water-works of a neighbouring local board. The descriptions given of the local conditions prevailing in both Maniktala and Cossipore-Chitpur leave no doubt that none of the recognised factors in the production of malarial disease are wanting. They are the most "water-logged" of the whole series, the ground water-level being on the average only five feet from the surface in February, and in both places it is said to rise to within one or two feet of the surface in the rains; the areas are studded with open tanks, and the larvæ of anopheles were found in abundance. These two towns, as already stated, differ from the rest in two particulars only, viz., in the possession of a filtered water-supply, and in the comparative freedom from the evidences of malaria. Where, further, certain well-defined parts of other towns yield approximate results in regard to the percentage of cases of enlarged spleen, such relative immunity is associated with a similar water-supply. On the other hand, the towns which are entirely dependent on open surface tanks for drinking water yield, without exception, the highest spleen rates, while river water supplies appear to be associated with intermediate rates; the tabulated results indeed go to show that the average rate for river-water drinkers is double, while that for tank-water drinkers is nearly treble that found among the consumers of filtered water.

It was impossible in the time at command to search all the pools and tanks in an area of many square miles, and it was therefore decided to map out all the surface water collections in a smaller typical area and examine them systematically, and a portion of Maniktala was chosen for this purpose. The larvæ of anopheles were found in abundance in tanks containing fish, in smaller pools, and in roadside drains which were supplied with water from the water-service stand-pipes, a fact of interest as bearing on the question of a suggested increase in the fever-rate in certain localities elsewhere, subsequent to the introduction of filtered water-supplies. It may be admitted that figures can be quoted in support of such an increase, and if the increase were real it is obvious that the view put forward by Captain Rogers would be directly traversed, and that a cogent argument would be adduced in favour of the direct inoculation theory of malaria infection. This is a question which is being investigated, but it may be advisable to indicate some of the difficulties attending an enquiry apparently so simple.

The causes of an increased death-rate subsequent to the introduction of an improved water-supply may be roughly distinguished as apparent and real; apparent where the increase is due to misleading figures, and real where there has been an actual increase in the ratio of deaths. As regards the former, we must note that registration was, and is, defective nearly everywhere, and most of all in municipal towns, but it is gradually improving.

Registration may have been specially defective in a town up till the time when, a considerable capital having been sunk in water-works, the attention of the local authority is aroused, greater interest is taken in the collection of vital statistics, and the recorded rates rise.

In every case disturbance is caused by the increase in population during inter-censal periods; the ratios, if the deaths continue only to be registered in the same proportion, must get apparently higher, though the actual death-rate may be really lower. A similar disturbance may be caused by an alteration of the municipal area to include or exclude either a very healthy or a very unhealthy suburb; in such cases comparison of the figures before and after cannot reasonably be made. A population may increase by immigration as a direct result of the convenience created by the introduction of water-works, and the ratios calculated on the census population will be vitiated.

Real increases may be brought about in cases where, although the supply is new, there is no improvement in the quality of the water consumed, and again where other causes enter to nullify the good effect of the improved supply. For instance, where the new supply exists side by side with the old, which is practically the case nearly everywhere, there is a tendency for the latter to become worse because less attention is paid to its conservancy. The average consumption per head in the large towns now in possession of water-works is obviously inadequate for all purposes, and natives have hardy prejudices in favour of their own house-wells for the supply for personal consumption. Again, a good public water-supply is open to very special risks, and if not under competent survey and management may disseminate widespread disease. Instances of factors which go to nullify the expected benefits of a good public system are where no arrangements are made to carry off the increased amount of water and waste introduced; water-logging of the soil from inadequate drainage results. And lastly, as a result of the introduction of a good and convenient water-supply, there may be overcrowding in certain parts of the town and deteriorated health, especially among infants, who furnish, roughly, from one-fourth to one-third of the total number of deaths.

It will be seen that in order to distinguish the real from the apparent effects of the introduction of a new system of water-supply, investigation must be very carefully and shrewdly conducted on the spot, in each case, by persons who are thoroughly acquainted with all the facts and competent to appraise their value and effect.

To return to the Bengal investigation: it is stated that just half of the 30 tanks in the area mapped out contained the larvæ of anopheles, in spite of the fact that all contained fish, a co-existence confirmed by observations made elsewhere. It is however to be borne in mind that the search was carried out in February, a time when fever is at its minimum prevalence, and it may possibly be that the particular species of anopheles found is not an effective host for the parasite, or that these were not, at the time, harbouring the parasite; further observations in this area will, it is hoped, be made during the ensuing rainy season and autumn when fever is rife.

Lastly, a comparison of the fever rates, based on the returns of ten of the principal dispensaries for the last six years, with the monthly rainfall records, when both were plotted on charts for the different areas, failed to indicate any definite relationship between the two; nor was a similar attempt to trace the effect of waterlogging of the soil, as indicated by the ground water-level, more successful.

It is to be observed that enlargement of the spleen is rather an evidence of past and confirmed malarial infection, than of the present active phase of the disease, nor does the present stage of our knowledge permit us to affirm an exclusive casual relation between the one and the other; and the value of these observations, which require to be confirmed elsewhere and to be supplemented by a laborious comparative series of clinical blood examinations, must at present be held to be, so far, discounted. What they certainly go to prove is that chronic enlargement of the spleen is definitely associated with the drinking of impure water, and so far as we can eliminate all other casual factors in the production of this pathological phenomenon, by so much will Captain Rogers' main thesis be established. At the same time the very striking relation between the spleen-rate and the death-rate from "fever" in the locality in question is very difficult to account for on any other hypothesis than that the former is a definite index of the prevalence of malaria. Again, it may be admitted that the evidence derived from the collation of meteorological and vital statistics is of a very doubtful value, where the diagnosis of fevers is unreliable, and where relapses cannot be distinguished from fresh infections, and no solution of a problem of such complexity can be expected from such data *per se*; but, under certain circumstances of time, place and observer they may have a real contributory value, when combined with research into the seasonal and local distribution of the definitive host, when we bear in mind the influence of meteorological factors on both the host and the parasite. It may be added that a recent writer in the *Berliner Klinische Wochenschrift*, in discussing the subject of malarial fevers in the Prussian army, comes independently to the suggestion of an apparent association between the general prevalence of the disease and the quality of the drinking-water consumed.

Meanwhile it is satisfactory to note that the clinical and pathological aspects of the subject are not neglected. The excellent work of the late Captain Murray, I.M.S., on the Punjab fevers,* has been followed recently by a careful and instructive investigation by Captain Fearnside, I.M.S., into the fatal form of malaria which has long been prevalent in

* "Scientific Memoirs by Medical Officers of the Army of India," Part X, 1897.

the Central Jail at Rajahmundry (Madras). The persistent heavy death-rate in this institution had been ascribed to Beri-Beri, and in the lucid summary the author presents of the medical history of this large institution we encounter the familiar problem of the etiology of a fatal form of fever, the outstanding symptoms of which are a combination of anæmia, dropsy, and an ill-defined neuritis. The subject is one of great interest, not only for its local and intrinsic importance, but in view of its bearing on the question of the pathological significance of certain forms of tropical disease which have been confused and have given rise to controversy, viz., Beri-Beri, Kala-Azar, Anchylostomiasis and pernicious malaria.* It is impossible within the limits of the space at command to follow Captain Fearnside throughout the exhaustive discussion he submits of his clinical and pathological observations. In a critical analysis of the results of 407 autopsies, he presents a vivid survey of the more remote effects of chronic malarial infection upon the various organs, and thereby elucidates the varying clinical aspects of a fatal form of disease which is familiar to medical officers of jails, and which when widely prevalent among the population at large, in certain areas, has been referred to different specific causes. This is supplemented by a careful account of the numerous examinations of the blood and of the intestinal dejecta made in cases representing every form of fever, including a large number of cases that would previously have been classed as Beri-Beri. One or other form of the malaria parasite was found in all, while the presence of the *ankylostoma duodenale* was established in 75 per cent., and an analysis of the research shows how constantly the supposed Beri-Beri was associated with the malignant varieties of the hæmatozoon in combination with the duodenal worm. An interesting observation is the fact noted that prisoners belonging to certain indigenous hill tribes are specially prone to harbour a malignant crescent-forming parasite; in times of scarcity large numbers of these poor people are admitted into jail, and the more fatal form of the disease becomes epidemic. Further observations with the object of elucidating the phenomena of relapses and of re-infection are being carried out; meanwhile Captain Fearnside has confirmed Ross' experiments on the proteosoma-infection of birds and on the development of the human parasite in anopheles. Altogether this research has a notable value as being the first endeavour to study the ravages of malaria in a large Indian prison under scientific conditions.

Mediterranean or Undulant Fever.—Those who have devoted study to the etiology of Malta or Undulant fever have long held the opinion that the distribution of the disease is not confined to the shores and islands of the Mediterranean. The simple clinical test made available by the ingenuity of Professor Wright of Netley had, so long ago as 1897, demonstrated the existence of the disease in patients invalided from India, no less than 10 cases in the first instance having yielded the specific reaction. These and subsequent observations which are summed up in an article by Captain Lamb, I.M.S., in the *Indian Medical Gazette* for September, 1900, leave no doubt that Undulant fever has a very wide distribution in the tropical and sub-tropical zones, cases having been identified in places so far apart as Puerto Rico in the West to Calcutta in the East. It is a notable fact as regards its distribution that in India it has been found in a large and increasing number of cases, not only in the large towns of the plains, but also in the hill stations of the Himalayas at an altitude of 7,000 feet.

There is already abundant evidence that the disease is not confined to Europeans; although observations on natives of this country have only recently been begun, there can be no doubt, from the positive results already obtained, that they are by no means rarely affected. Many cases of so-called simple continued fever of malarial remittent and of aberrant typhoid fever will doubtless be rescued from the limbo* of this unsatisfactory classification, and while further observations on the distribution and the prevalence of the disease must be awaited, we may even now anticipate an important advance in our knowledge of a class of fevers that has long reproached our ignorance, and our nosology.

Cerebro-Spinal Meningitis.—A reference to page 91 of this Report will afford some information as to the occurrence of Cerebro-spinal meningitis in the jails of India during the last few years.† It cannot, however, be reasonably doubted that this is a disease with which we have long had to reckon, but which has, until comparatively recent years, eluded diagnosis. Hirsch, whose survey of its geographical distribution extends to the year 1886, takes no account of its occurrence in India, but the annals of

---

* *See* article Kala-Azar, Section X, Annual Report of Sanitary Commissioner with the Government of India, 1897.

† Not reprinted in this Abstract.

epidemiology afford striking evidence of outbreaks, which in the light of recent knowledge, must be referred to this specific infection. For instance, the outbreaks of the "new fever of a pernicious type" in Wardha (Central Provinces) in 1881 rendered classic by an extended reference in Creighton's *History of Epidemics*, must now be classed as one of epidemic cerebro-spinal meningitis. Not only as regards the clinical symptoms, but in respect of the general conditions accompanying the epidemic, we find a striking agreement with those which recent experience has taught us to associate with outbreaks in this country. But it is among the medical records of the jail population that, as might be expected, we find the most definite and undeniable evidence of the disease, while characteristic outbreaks are of constant occurrence among the emigrant coolies who congregate at the Calcutta depôts for embarkation for the West Indian plantations. A careful account of the first recorded cases in India is given in a paper presented to the first Indian Medical Congress (1894) by Surgeon-Lieutenant-Colonel Moorhead, I.M.S., and the record is summarised and supplemented by Major W. J. Buchanan, I.M.S., in the *Journal of Tropical Medicine* for August, 1898, and in subsequent articles in the *Indian Medical Gazette*. To the latter officer must be ascribed the credit of establishing the identity of the disease as met with in India, with the cerebro-spinal meningitis of America and Europe, by the discovery of the *diplococcus intracellularis* (Weichselbaum) in the cellular elements of the fluid withdrawn by spinal puncture, his results having been confirmed by the Professor of Pathology at the Calcutta Medical College. And it is to further observations on the etiology of the disease made by Major Buchanan and Captain Stevens, I.M.S., during recent outbreaks in the Bhagalpur Jail that it is desired to draw attention.

Since January, 1897, this jail has been the scene of a succession of cases, 47 in all, which may be grouped into three distinct outbreaks; the first from January 11th to April 18th, 1897; the second from October 17th, 1897, till April 20th, 1898; and the third from August 22nd, 1899, till August 1900. The monthly incidence is important and was as follows: January, 2 cases; February, 2; March, 5; April, 25; May, 2; June, none; July, 2; August, 1; September, 1; October, 3; November, none; and December, 2 cases. It may be mentioned that the average annual rainfall of Behar is approximately 50 inches, falling on an average of 75 days. In the whole November-April period, 6 months, there is an average fall of only 2·3 inches and only 8 rainy days altogether on the average. The months of March and April are distinguished by having by far the greatest daily range of temperature, with an average minimum of 63° (Blandford).

Major Buchanan, starting with the assumption that the *diplococcus intracellularis* is the cause of the disease, was struck by the fact alleged by Germano, as the result of his researches into the viability of pathogenic organisms in dust (*Zeitschrift für Hygiene*, XXVI, pp. 228-291), that this diplococcus is the most resistant of all known pathogenic microbes to the effect of natural drying processes, and consequently the most viable in dust, "and capable of setting up infection in this way." Captain Stevens had independently arrived at the conclusion that there exists a direct connexion between dust and the disease in question. Enquiry was directed to the nature of the occupations of the prisoners attacked, and it was found that out of an average daily strength of some 650 men employed in labour which exposed them to dust in a marked degree, 44 out of the 47 cases occurred; only 3 cases, therefore, remain to be accounted for among a population, averaging 1,000 in number, whose work was done in comparatively dust-free surroundings in the clean factories whose walls and floors are coated with moist clay, constantly renewed. It is also noted that certain classes of prisoners who are habitually confined in certain parts of the jail enclosure, which are surrounded by high walls built close to the barracks, have hitherto been free from attacks. On the other hand twenty-four of the cases occurred amongst men exposed to wind-borne dust in road making, gardening, sweeping, building and dismantling old buildings, digging and working lime-kilns. No less than 16 cases arose among those occupied in "paddy-husking," in wheat-grinding and in cleaning food-grains; the remaining 4 are noted as cook's attendants, who are exposed to an atmosphere thick with dust. It will be remembered that the epidemic among the Soudanese troops in Khartoum in 1898 was associated with the work of dismantling old eastern houses and of removing the dust-laden roofs thereof.

The marked incidence of the disease in the dry, rainless months strongly supports this *prima facie* view of a connexion with germ-laden dust; sporadic cases of the disease among the general community outside the jail are known to occur, and many doubtless remain undiscovered owing to the absence of skilled medical attendance. The seven cases

recorded in the monsoon period (June to October), occurred among prisoners employed in cleaning stored food-grains. April, the month of election for the disease, is notoriously the period of drought and strong west winds.

The type of all outbreaks in the Indian jails appears to suggest an epidemic source of infection; the same institutions are repeatedly attacked, while information is accumulating of synchronous sporadic cases among the general population in the immediate environment. At the same time the evidence of infection direct from case to case is difficult to establish; cases drop in at intervals with no apparent connexion *inter se* and no widespread general epidemic occurs. Lastly, removal of a community into open camp has in several instances failed to influence the cause of the disease, and although overcrowding may undoubtedly be a factor in its spread when once it has entered a barrack, as is to be expected in the case of an acute specific fever, the "cause" of which is contained in the nasal discharges, yet enquiry as to any definite relation with overcrowding has generally yielded negative results. In many respects a likeness to epidemic pneumonia suggests itself. It cannot, however, be doubted that in the recognition of this disease—and further observation will assuredly demonstrate that it is more widespread than our present scanty records would indicate—we are enabled to differentiate one more specific infection from the mass of tropical fevers. It is quite possible that some of the fatal cases returned as heat-stroke, heat-apoplexy and sunstroke, as well as some recorded as simple meningitis, may really be due to the disease in question. The routine observation of "Kernig's symptom" in all such cases would be a useful addition to other clinical tests, for although it may not prove to be absolutely pathognomonic for specific cerebro-spinal meningitis, the best authorities in this country are inclined to attach great diagnostic importance to it.

Enteric Fever and Dust.—It need scarcely be said that too much stress is not to be laid upon these scanty and purely epidemiological considerations, which must be held to have merely a suggestive value as indicating a promising field for exact research. Some striking evidence in connexion with the excessive prevalence of enteric fever among the European troops at Quetta in 1898, which has suggested a casual relation between infected dust and the disease, has led a recent writer to look into the seasonal incidence of enteric fever as it occurs in certain of the large geographical "groups" with the result of further emphasizing the possibility of this source of infection. And it is true that if certain selected areas are taken, and if the admissions to hospital are plotted upon a scheme with the rainfall, there appears to be a notable incidence of the disease upon the rainless months of the year. But the limitations of the epidemiological method of enquiry are soon exposed, if we pursue the enquiry into other areas and over a series of years with their varying meteorological conditions. The factors are extremely complex and the data unreliable; while, for instance, the terms simple continued fever and remittent fever are still in use to a very large but unequal extent, it can scarcely be doubted that while many cases of enteric escape recognition, other specific forms are therein included, *e.g.*, Malta fever. But beyond this it will be found that the seasonal incidence of the admission for enteric gives a characteristic but different curve in nearly every separate geographical group. Whereas in the Punjab and on the frontier, the disease appears to be strictly limited to the rainless months and to vanish with the onset and continuation of the light and intermittent rainfall, on the other hand, in the Bombay Command it is decidedly most prevalent during the heavy and continuous monsoon weather; while in the North-Western Provinces and in Southern India there is a marked double rise in the curve,—one during the dry, hot weather, and the other during the rains—suggesting the possibility of the influence of dust in the one case, and of pollution of the water supplies in the other. Many questions are opened up, *viz.*, the nature of the soil, and of the water-sources, the height and fluctuation of the ground-water in polluted soil; for on a friable polluted soil with deep wells and a low ground water, dust might reasonably be expected to be a vehicle strongly open to suspicion, whereas on a consistent clay or rocky soil with surface water-supplies, the flushing of the polluted surface by rainfall would point to the probability of the infection of the drinking-water. There are, of course, other factors to be taken into account, such as the greater or less prevalence of flies at different seasons and in different places, but enough has been said here to show that the problem is a complex one, and not to be solved by an appeal to certain broad epidemiological facts, though these doubtless have their value.

Fevers in the Kumaon Hills.—Finally, a brief reference may be made to the observations made during a visit to the Kumaon hills in 1899, by Captain Rogers, I.M.S., into the disease called "sanjar" by the natives, and which has been thought to signify the endemic bubonic plague of these highlands. It is true that previous enquirers have

endeavoured to distinguish between "sanjar" and "mahamari," but hitherto they have had to rely on the confused statements of the ignorant survivors, as intelligence of an outbreak of fatal disease in these small and remote communities is long in reaching the authorities, and competent medical aid is not immediately available.

Captain Rogers was more fortunate, and his description of the clinical course of the fever and his discovery of the *Spirillum Obermeieri* in the blood of a patient have made it clear that "sanjar," in one of its forms at least, is true relapsing fever, although the term is applied indiscriminately to various infectious diseases which find all the conditions favourable to their rise and propagation in the intensely insanitary surroundings of these poor hill-folk.

The term "mahamari," on the other hand, connotes a more fatal and fulminant epidemic, either true plague, or typhus, or even cholera, and it is hoped that timely information of the next outbreak will make it possible to investigate the subject further.

Preventive inoculation for Enteric Fever.—In concluding these discursive remarks on recent progress in our knowledge of Indian fevers, it will be interesting to give some figures showing the results attained so far by the process of inoculation for enteric fever introduced by Professor Wright of the Army Medical School, Netley. It will be observed that the results of the operations have been compared in two series, *viz.*, in the corps in which inoculations were carried out and in the whole body of the European army, in order to obviate any fallacy which might arise from a comparison instituted between populations not exposed to the same conditions. It must be admitted that it is impossible to make a scrupulously exact comparison of the conditions which in their sum involve a liability to, or an immunity against, enteric fever. For exact deductions we should have to take equal numbers of men of sufficient daily average strength, of equal age-periods, and of equal length of residence in places equally presenting the sources of infection. But it is submitted that the numbers from which the present data are drawn are sufficiently large to compensate for the factors which tend to vitiate the ideal of an exact comparison, and even if it be held that their interest is, at this stage, rather of a provisional nature, the immense importance of the subject demands that every fact which tells for or against the process should be presented without delay.

Enteric Fever and inoculation in India in 1899.

European Army of India.	Strength.	Number of men inoculated.	Number of men not inoculated.	Cases of Enteric Fever.				Percentage to Strength.				Difference between A and B in favour of A.		Percentage decrease in favour of A.	
				Amongst the men inoculated.		Amongst the men not inoculated.		Amongst the men inoculated. A.		Amongst the men not inoculated. B.					
				Admitted.	Died.	Admitted.	Died.	Admitted.	Died.	Admitted.	Died.				
												A.	D.	A.	D.
Corps in which inoculations were performed	30,353	4,502	25,851	44	9	657	146	·98	·20	2·54	·56	1·56	·36	61·4	64·3
European army of India ...	67,697	4,502	63,195	44	9	1,348	329	·98	·20	2·13	·54	1·15	·34	54·0	63·0

It is to be noted that so far as these figures go, the value of the process is demonstrated most notably on its prophylactic side; as regards the case mortality, however, there is also some appreciable difference. Among the inoculated it was 20·45 per cent., while among the uninoculated it was slightly higher, *viz.*, 22·22 per cent. in the corps in which inoculations were performed, while 25·14 per cent. in the army as a whole. For the rest the table may be allowed to speak for itself.

Tuberculosis in India.—In the Appendix to this section in last year's report some remarks by Lieutenant-Colonel Crombie, M.D., I.M.S., on the subject of tuberculosis in India, were included in a report made by that officer on the proceedings of the Congress on Tuberculosis held in Berlin in May, 1899. The general conclusion arrived at was that the disease was notably less prevalent, especially among children, in India than in Europe, but at the same time an increase among the jail section of the population was not overlooked. There are obvious reasons why the pathology of fatal disease among the

large adult population of Indian jails should be more closely followed and accurately recorded than is the case for any other class; prisoners are constantly under medical supervision, and in all fatal cases a post-mortem examination is the rule. As long ago as 1848, Alan Webb pointed out how easy it was to overlook tuberculosis in natives dying of dysentery, diarrhœa and other wasting diseases, and it must be admitted that an examination of the jail death returns from phthisis pulmonalis for the last 20 years leaves some doubt as to how far the very decided and progressive rise therein shown connotes a real increase, or to what extent it depends on more accurate diagnosis. Subjoined is a tabular statement that may assist in throwing some light on the subject; it gives the ratios per 1,000 of deaths from tubercle of the lungs, and from anæmia and debility in each provincial group of jails for the last four quinquennial periods.

Ratio of deaths from Tubercle and Anæmia and Debility in jails during the four quinquennia 1880 *to* 1899.

Province.		Ratio of Deaths per 1,000 of Population during the Years.			
		1880–84.	1885–89.	1890–94.	1895–99.
Burma	Tubercle	1·47	3·18	2·51	3·51
	Anæmia and Debility ...	2·81	4·63	1·08	0·37
Assam	Tubercle	0·64	1·49	0·17	1·40
	Anæmia and Debility ...	4·13	4·43	4·63	4·26
Bengal	Tubercle	4·14	3·39	2·72	3·41
	Anæmia and Debility ...	3·80	1·92	1·55	0·93
North-Western Provinces and Oudh.	Tubercle	1·84	1·81	1·80	2·58
	Anæmia and Debility ...	1·73	2·27	1·97	2·78
Punjab	Tubercle	1·27	1·73	1·76	2·41
	Anæmia and Debility ...	1·91	1·02	0·33	0·29
Bombay	Tubercle	1·72	1·28	0·69	2·57
	Anæmia and Debility ...	2·25	1·82	2·36	1·03
Berar	Tubercle	1·09	1·37	0·77	1·32
	Anæmia and Debility ...	0·47	0·58	0·96	3·20
Central Provinces ...	Tubercle	0·90	1·36	0·38	3·73
	Anæmia and Debility ...	6·58	5·73	2·15	3·92
Madras	Tubercle	1·60	1·88	1·46	3·22
	Anæmia and Debility ...	3·42	2·35	2·50	0·12
All India	Tubercle	1·63	1·94	1·38	2·68
	Anæmia and Debility ...	3·01	2·75	1·75	1·88

Two important conclusions, at least, are deducible from these figures, viz., first that improved diagnosis has contributed largely to the nominal increase in the tubercle death-rate, for we see that as this latter rises the deaths allotted to anæmia and debility decline in approximately equal ratio, the combined death-rate from the two causes being much the same in the first period as in the last. And, secondly, we arrive at the fact, which is contrary to the accepted belief that the death-rate among adult natives of India living under excellent hygienic conditions is notably higher than that of England and Wales

among the population of the same age-periods, viz., 15–55. In India the ratio per 1,000 of average strength in 1899 was 2·49, while for England and Wales in 1898 it was 2·04.* There is fortunately good ground for the belief that the increase is not real to any appreciable extent, and that the prevalence of the disease can be traced, not to the conditions of jail life, though these, doubtless, are not favourable to amelioration and recovery when the prisoner is admitted with the disease, but to the general low standard of vitality among the poorer classes who furnish the crimnal population. A vegetarian diet, poor in the nitrogenous and fatty elements, defects of clothing in a climate subject to an enormous diurnal and annual range and the overcrowding in dark, damp and dust-laden huts, which is the lot of the majority during the colder months and during the rains, are all factors acknowledged as the most potent everywhere as predisposing to the disease. It is perhaps needless to add that all possible measures of prevention are being employed.

Special Sanitary Officers for Commands:—In these reports for the last three years a *précis* has appeared of the results of the investigations of the three special sanitary officers, who have been recently attached to two of the largest military districts and to army head-quarters in India, and whose duty it has been to enquire into special outbreaks of disease, and to carry out experimental observations with a view to the elucidation of the chief sanitary problems in cantonments. Their work has been strictly practical in its aim, and the results have proved so valuable that in an order just published the Government of India have decided to increase their number to four, and to attach one to each of the commands. As heretofore, these officers will be selected from the Royal Army Medical Corps and will be required to have undergone special training in sanitary science and to possess a diploma in public health.

In addition to the appointment of these officers, and in order to ensure continuity of work in their laboratories during their absences, which must necessarily be frequent, arrangements will be made to associate with each of them a medical officer from the station hospital at their head-quarters, who will be relieved for this purpose of some of his ordinary duties. It is hoped that in the future these assistant officers will be usefully employed on sanitary work during field operations. With a view also to further extend the advantages of microscopic examinations and scientific advice in sanitary matters, small and inexpensive laboratories will be established at the head-quarters of each district (except the Punjab Frontier Force and Assam, where there are no British troops), under the superintendence of the medical officer in charge of the station hospital. The duties of the officers in charge of these district laboratories will be to conduct such investigations as may be within their powers, with special reference to sanitation, and to render assistance to the sanitary officer of the command whenever necessary. The latter will supervise the district laboratories, direct the efforts of the officers in charge, and encourage the development of bacteriological research as much as possible.

There cannot be any question that this action, taken on the advice of the Principal Medical Officer, Her Majesty's Forces in India, will be fruitful in important practical benefit to the health of the troops, and in contributions to the elucidation of the problems of tropical disease.

And further, it may be noted that the establishment and early inauguration of the Central Bacteriological Institute for India, is engaging immediate attention. There will probably be some delay before affiliated provincial institutes, which are to complete the project, become accomplished facts. But the scheme has been cordially approved and moves to completion, and the Government and the country are to be congratulated equally on a measure which cannot but prove to be of enormous benefit to medical science, and so promote the common weal.

The Pasteur Institute.—The public-spirited enterprise of the private association formed several years ago for the purpose of providing treatment for persons bitten by rabid dogs in India, on the Pasteur system, has at last achieved its purpose. On August 9th, 1900, the Indian Pasteur Institute was opened for active operations at Kasauli, a hill cantonment and sanitarium in the Himalayas, near Simla. This practical issue after years of effort is largely due to the active interest taken in the movement by the Principal Medical Officer, Her Majesty's Forces in India, who was able to place the services of Major Semple, R.A.M.C., at the disposal of the Committee, and already a large number of patients, both European and Native have undergone treatment at his hands.

---

* Phthisis; Registrar-General's Report, 1898.

The Red Sea Pilgrim Traffic.—The quarantine station on the island of Camaran was opened for the reception of pilgrims for the Haj of 1898–99 on 25th November of the former year. The number of pilgrims from all parts accommodated during the season was 14,074, against 15,228 and 14,210 in the two previous seasons, respectively.

The continued presence of plague in India rendered it incumbent on the part of the Government of this country to maintain the precautions which had been enforced during the previous year, and which were fully detailed in this Report for 1898. Briefly, it may be recalled that the Notification of November 10th, 1898, ordained that no person resident in the Bombay Presidency (excluding Sind, but including its port, Karachi), the Mysore Presidency, Mysore, the Hyderabad States and Coorg, would be permitted to embark for Mecca from any port in India save Chittagong, and then only after a period of detention for medical observation. Local Governments and Administrations were further directed to advise all intending pilgrims to defer their journey until a more favourable season.

The effect of these measures in limiting the exodus from India was everywhere apparent. His Highness the Nizam of Hyderabad fell in with the views of the Government, and agreed that his Mussalman subjects should defer their pious journey; and in consequence of the limitation of embarkation to the one port of Chittagong, certain Javanese pilgrims who arrived at Bombay viâ Madras, and who were unaware of this arrangement, declined to prolong their journey to Chittagong and elected to return to Java forthwith.

A further precaution, instituted for the first time, was the disinfection of all clothing and effects before embarkation was permitted at Chittagong, a measure that appears to have been carried out very carefully and successfully.

As a consequence of these deterrent measures, moral and practical, only two ships were despatched from India with pilgrims during the season, and these left Chittagong on the 25th January and the 28th February, 1899, with 740 and 706 Hajjis respectively. Altogether 1,833 Natives of India and 70 Afghans arrived at Camaran to undergo quarantine, prior to proceeding to Mecca, as compared with 890 and 124 respectively in the previous year, the number in excess of those who embarked at Chittagong being accounted for by pilgrims from the Straits Settlements and from Persian ports.

On the arrival of one of the two ships from India at Camaran, a pilgrim who had been under treatment for asthma and remittent fever during the voyage, which occupied some 46 days, was suspected to be suffering from plague, and an examination of his sputa is alleged to have revealed the presence of the specific bacilli. Doubt is thrown upon the diagnosis by the vice-consul at Jeddah, a medical man, and it is satisfactory to record that no other case, either on board the pilgrim ships or in the Lazaret, gave rise to suspicion that the disease had escaped the vigilance of the authorities.

Plague was, unfortunately, present in Jeddah, the first case having been discovered on the 22nd February, 1899, that is long before the arrival of pilgrims from India. Pilgrims were nevertheless allowed to enter the town, but only for the briefest period compatible with the necessary business for the necessary journey to Mecca, and no case of the disease was reported among the natives of India. One or two cases of plague are said to have occurred at Mecca itself, but they were clearly imported from Jeddah.

Return of the Pilgrims.—Three vessels left Jeddah for the port of Calcutta during the year, from one of which the pilgrims were landed, contrary to instructions, before inspection by the Health Officer. The other two brought 748 Indian pilgrims, who, after inspection and thorough disinfection of their effects and clothing, were despatched by rail under police escort to their destinations. Javanese pilgrims, to the number of 338, were not allowed to land, but transferred at once to a vessel which sailed forthwith for Singapore. The health on board these ships during the return voyage had been exceptionally good. Eleven vessels, bringing in all 862 pilgrims from Jeddah viâ Aden and other routes, entered the port of Bombay during the year. Only five deaths had occurred among this number during the voyage, and these were clearly attributable to privation, there being no case of infectious disease. The baggage and clothing of all was disinfected on arrival at Bombay; the pilgrims living up-country were not allowed to enter the city, but were sent direct from the ships to their homes by rail at the expense of the Government.

ABSTRACT OF THE REPORT OF THE SANITARY COMMISSIONER FOR MADRAS FOR 1899.

(*Lieutenant-Colonel W. G. King, C.I.E.*)

General Population.

4. According to the census of 1891, the population of the Presidency is 35,641,828 (inclusive of Europeans and Eurasians); the estimated population is 38,256,526. 185,814 souls emigrated during 1899 to places beyond the Presidency, against 245,862 in 1898. Immigrations, when balanced against these figures, show that a decrease of the population occurred to the extent of 23,394. The "natural increase" of the population was 373,499. Of the total census population—which, unless otherwise stated, is referred to hereafter—only 33,565,859 inhabit areas where registration is conducted; or, in other words, of a population of 2,075,969 no vital statistical records are maintained. These represent chiefly inhabitants of mountain ranges, where the subordinate administrative machinery is not of the class that would enable a system of registration to be conducted efficiently. Necessarily, efficiency of registration in this Presidency is less in rural areas where registration is not compulsory than in municipalities, where it is so. Difficulties in rural areas are further accentuated by the existence of large tracts in several important districts, which are under semi-independent administration; from these, the punctual submission of statistical returns has ever been a matter of difficulty for the District officers concerned to enforce. In these special cases, as remarked in former reports, much improvement may be expected on the introduction of the Village Proprietary Act. In the meantime, more especially since 1897, Government has considered various proposals for the improvement of registration in rural areas. An outcome of these considerations has been the passing of the "Madras Registration of Births and Deaths Act" of 1899. Under this Act, it is intended not to at once bring under influence the whole of the rural tracts, but such as may from time to time be selected by Government. Registration of births and deaths is rendered compulsory. Provision is made for the appointment of Registrars, and for the granting of extracts from the registers free of charge. The latter is a point, the legal importance of which the average uneducated native is quite capable of appreciating, and which will therefore probably conduce greatly to the popularity of the measure. The difficulty in finding a sufficiently educated staff to secure a marked improvement even under the influence of this Act is, however, apparent, as anything approaching a specially organized staff would present financial difficulties not likely to be overcome. In the meantime, indubitably, ever increasing attention has been paid to the subject of correct registration by the Revenue Department. In inspecting the birth and death registers, the Revenue Department continues to receive material aid from Deputy Inspectors of Vaccination, District Medical and Sanitary officers, and from this office. During the year, the attention of Collectors was specially invited to the condition of registration in various villages within their respective districts in 78 instances. In the case of both districts and municipalities, irrespective of personal examination of the registers during ordinary inspection duties, I make it a point to draw attention to the variations in monthly returns when compared with previous years, directly the vital statistical returns compiled in this office are available for exhibition of results.

Births in Districts.—The total birth-rate for the Presidency is the highest on record, namely, 31·3 per 1,000. The following table shows that, with the exception of the deficient birth-rate for the year 1898 (which it was pointed out in the report for that year was due to the influence of famine on the population during 1896-97), there has been a

steady increase in the birth-rate registered—a result that must be ascribed to better attention to registration by all concerned :—

Table showing the total birth-rates for the Presidency from 1892 *to* 1899.

Years.	Birth-rate on the census population.*	Birth-rate on the estimated population.*	Years.	Birth-rate on the census population.*	Birth-rate on the estimated population.*
1892	25·1	24·4	1896	29·1	26·8
1893	26·9	25·9	1897	25·3	23·0†
1894	27·7	26·2	1898	24·6	22·0†
1895	28·9	27·1	1899	31·3	27·4

* Inclusive of Europeans and Eurasians both in the births and population.
† Famine influence.

It would, of course, be possible to ascribe this increase to the larger population dealt with in the inter-censal period than apparent when rates are reckoned upon the census population. I have, therefore, side by side with the results upon the census population, shown those on the estimated population. It will be seen that an increment is s evident that bears out my assertion.

Of a total of 22 districts, only Madura, South Arcot, Tanjore, Madras and Trichinopoly, exhibit a slight decrease ; in all other cases an increase in the birth-rate is shown. The rate is remarkably high in districts that suffered from famine in 1896-97, and where, consequently, there had been an increased infantile death-rate, and later a decrease in the birth-rate when compared with the previous year, although still below the average of these districts. The great feature in the severe famine of 1877 was that the adult population suffered severely, with the consequence that the birth-rate was decreased for a series of years, until the influx of a young population reaching the child-bearing age suddenly caused the birth-rate to rapidly increase, so that, whilst in the census of 1881, it was held that the normal birth-rate of the Presidency was 42·45 per 1,000, in the census of 1891 it was suggested that for at least a period it must have attained the rate of 55 per 1,000. But such conditions as occurred in the 1877 famine are never likely to again be faced by the population ; the wide distribution of railways and the better methods of organization of relief are such as should not be followed by a material increase of the death-rate of adults. It is, however, unlikely that the methods employed will ever be sufficiently developed to prevent a depression of the birth-rate, and an increase of the infantile death-rate. On the return of prosperity the famine population subjected to such conditions must be expected, as shown in the present instance, to develop an increased birth-rate, so that a famine combated on modern lines must not be looked upon as a "natural check" to the increase of populations. For example, the following shows the strides made in the birth-rate in the districts which were affected by famine :—

Name of District.	Average of previous five years.	Birth-rate during 1898.	Average yearly increase or decrease of the birth-rate in the previous five years.	Actual increase between 1898 and 1899.
Anantapur	28·3	24·8	— 0·2	6·5
Bellary	32·8	29·3	— 0·2	5·5
Cuddapah	27·3	23·3	+ 0·1	4·6
Ganjám	21·9	22·9	+ 0·9	8·8
Malabar	21·6	18·6	— 0·3	7·4
Vizagapatam	27·4	23·8	+ 0·3	13·4

At the same time, it is not claimed that a reaction after famine is the sole cause, as the increase is exhibited in districts other than those named, although it must be remembered, as pointed out in last year's report, that the depressed birth-rate did not confine itself solely to districts where famine had been officially declared—others suffered in a less degree from the high prices of food-grains, and exhibited increase of the infantile

death-rate and decreased birth-rate. To increased care in registration must be ascribed much of the result. The occurrence of marriages that had been deferred must also have had influence.

103·9 births of boys were registered to every one hundred births of girls. According to races the birth-rates were as follows:—Native Christians 26·5, Muhammadans 29·9 and Hindus 31·5, per 1,000 of their respective populations.

Deaths in Districts.—The total deaths for the Presidency amounted to 675,094, giving a rate of 20·1 per 1,000 on the census, and 17·6 per 1,000 on the estimated population. The following table shows under causation the percentage due to each disease. To enable a comparison to be conveniently made, the table is extended so as to include the previous seven years:—

Years.	Birth-rate per 1,000 of population.	Percentage of deaths from						Death-rate per 1,000 of population.
		Cholera.	Small-pox.	Fevers.	Dysentery and Diarrhœa.	Injuries.	All other causes.	
1892	25·1	10·5	5·8	37·4	4·3	1·5	40·5	22·3
1893	27·0	5·0	4·2	39·9	3·6	1·6	45·7	19·3
1894	27·7	6·3	1·7	40·2	3·7	1·7	46·4	20·0
1895	29·1	3·2	0·8	42·1	3·6	1·6	48·7	19·6
1896	29·9	7·1	1·4	38·6	3·7	1·6	47·6	20·6
1897	28·7	17·3	2·6	35·3	4·7	1·4	38·7	25·4
1898	27·4	9·4	2·9	35·6	4·2	1·6	46·3	21·0
1899	31·3	4·3	2·5	36·4	4·6	2·0	50·2	20·1

It is hopeless to attempt, under existing circumstances of registration, to criticise the death-rates reported from districts. They may possibly sink to the almost certainly ridiculous rate of 14·4 per 1,000 in Ganjám, or rise to nearly 30 per 1,000 in South Canara, without its being possible to state definitely what are the errors of omission and commission. The only criterion available is the approach to accuracy of the birth-rate, and the acknowledged existence of special diseases. One cause of deficient death-rate is certainly a tendency to ignore the deaths of infants below one year of age. This conclusion was forced upon me by the perusal of numerous abstracts of village registers furnished to this office by District Medical and Sanitary officers during their inspections. It was obvious that the death of an infant who had not managed to struggle through a year of life was often held unworthy of official recognition by the village officer, with the result of marring the total statistics supplied. To this subject I have drawn the attention of Collectors, and a demand for increased care by their village officers was promptly made by them. Although there is no reason to believe that the rate of 14·4 per 1,000 credited to Ganjám represents the facts of the case, it is evident a satisfactory fall in mortality has occurred. It will be remembered that in this district the fearful rate of 50·1 per 1,000 was reached in 1897—a result due to famine and small-pox, whilst in 1898 small-pox was again responsible for a heavy proportion of the total mortality, which amounted to 22·7 per 1,000.

Excluding Madras district—the circumstances of which do not permit it to be fairly compared with rural districts—the highest death-rate was registered in South Canara (29·9 per 1,000). This increased rate over the preceding year is accounted for by the larger proportion of fever registered. There is no reason to believe that the majority of these fever cases were not due to malaria, but it is well to remember that both in South Canara and Malabar typhoid fever is an acknowledged factor of the mortality amongst natives. In Bellary the increase of 1·9 per 1,000 over the previous year was due to the increased death-rate from cholera. In other instances the fluctuations with reference to previous recorded rates are of little importance, and in 14 out of a total of 22 districts, the variation represents a decrease.

It has been frequently remarked in the reports of this office that the rates for rural towns are specially untrustworthy, and the cause has been ascribed to the impossibility of

village officers attending to registration where the population had reached the limits which accompany the definition of a "Town," namely 10,000 inhabitants. It is specially in dealing with these towns that the benefit of the Registration Act of 1899 above referred to should be felt, if special Registrars be supplied.

The infantile death-rate was 159·0 per 1,000 of births—a result contrasting favourably with that of the previous year (163·3).

Births in Municipalities.—As in the case of rural areas, the total birth-rate of municipalities has shown an increase, it being 37·0 against 34·9 per 1,000 of the previous year. This result testifies well to better activity in registration in rural areas, where the increase over the previous year is 5·4 against 2·1 per 1,000 for municipalities. In both, the rates still fall far short of what, as already observed in discussing district rates, must be held as the standard birth-rate of this Presidency. The total average has been much impaired by such glaring instances of decline of the birth-rate as exhibited by Vellore (8·8 per 1,000) and Walajapet (8·4 per 1,000) below the average. In both cases the rates for the previous year were also unsatisfactory and showed a decline—due undoubtedly to careless registration for which there was no excuse—but in 1899, the obtaining of correct statistics must have been much impeded by the existence of plague in both towns. The continued low rate registered in Cuddapah is due to a large extent to the usual absence of fecundity in a population stricken with malaria. In face of the re-action in the birth-rate which has been exhibited in the district of Cuddapah (an increase of 4·6 per 1,000 over the previous year) and other areas that were effected with famine, it is exceedingly unlikely that the late famine still exhibits its influence upon the birth-rate of this town. Consequently, the absurd rate of 14·3 per 1,000—a decline of no less than 7·3 per 1,000 below the very poor average of 21·6 for the previous five years—must be regarded as very largely due to apathy on the part of the Municipal Council. Other towns showing notable decrease for which there is no reasonable excuse are Cuddalore, Madura. Mannárgudi, Palamcottah, Salem, Tirupati, Cochin and Conjeeveram. When compared with the previous year, it is found that increase of the birth-rate has been attained in 44 towns against 39 in that year. It is satisfactory to find that Cocanada, Berhampur and Parlákimedi, which for so long a period exhibited markedly inferior results, have now secured a better approach to the normal rate. There remains, however, much room for improvement. Of the total of 59 municipalities, 16 show rates above 30, 21 above 35, 11 above 40 and 5 above 45.

Deaths in Municipalities.—The average death-rate for the year has been 30·7—a decrease of 0·3 below the average for the past five years, and 1·2 below the previous year. In 28 instances there has been a decrease in the total death-rate; in 29, there has been an increase. In Anantapur and Palni, seeing that there has been an increase of the birth-rate, the fall to 16·5 per 1,000 from 21·0, and to 17·5 per 1,000 from 31·4, respectively, of the previous year is suspicious of imperfect registration of deaths, although the absence of epidemic cholera in Palni during the year under review contributes to the sharpness of the contrast. The same may be said of Dindigul where, although the birth-rate has increased 9·7 per 1,000 for the year, the death-rate remains the same as during 1898, namely 18·9.

In Masulipatam, Ellore, Máyavaram, Vizagapatam, Bimlipatam and Vizianagram the increased death-rate, when judged side by side with the increased birth-rate, merely implies better care in registration. In Karúr, Gudiyáttam, Salem, Vániyambádi, Kumbakónam, and Tinnevelly, the chief cause of increased mortality was cholera. In Vellore and Tiruppattúr, both cholera and plague caused the increase, whilst in Walajapet it was chiefly due to plague. In the Madras town, there was registered a satisfactory fall when compared with the previous year of 6·7 per 1,000, and of 0·3 per 1,000 below the average of the previous five years. Madras has, on account of the necessity for keeping it prepared for the advent of plague, never had bestowed upon it so great attention hitherto as to the executive details of sanitary administration. Seeing that the meteorological conditions were fairly normal in this locality, it is probable that beneficial influence has been exercised upon the general health of the people, although a decrease of 1·65 per 1,000 in the cholera death-rate has contributed mainly to this result.

The total average infantile death-rate for Municipalities was 223·9 per 1,000 of births, against 229·5 in the past year—a measure of improvement that may be ascribed to better ability of the people to obtain luxuries owing to easier prices of grains. The causes of high rate of infantile mortality in periods of normal prices of food-grains have, from time to time, been discussed in my Annual Reports, and therefore need not be now entered into. It suffices to remember that no more delicate test of the hygienic condition of a

population and its surroundings exists than exhibited by the infantile death-rate—more especially with reference to the cleanliness of the soil. Judged by this rough standard, theoretically, it may be concluded that the towns of Tinnevelly, Tuticorin, Masulipatam, Madras, Negapatam, Madura, Ellore, Bezwada, Chingleput, Kumbakónam and Periyakulam must possess foul soils, as in practice undoubtedly they do.

Chief Diseases.

Cholera.—The deaths from cholera were but 0·9 per 1,000 of the population, against 2·0 per 1,000 in the previous year. The greatest number of deaths occurred in Salem, where they amounted to 5,568 (2·8 per 1,000 of the population), in Tanjore, where they were 5,864 (2·6 per 1,000 of the population), and Trichinopoly, where they were 3,287 (2·4 per 1,000 of the population). As has been pointed out in former reports, the incidence of mortality was, as usual, in the south-west monsoon districts, greatest during the south-west monsoon, and in the north-east monsoon districts, during the north-east monsoon. Commencing with 1894, when the facts were illustrated by diagrams representing the average for the preceding ten years, with the exception of the slight variation in 1898, the truth of this observation has been annually proved by the statistics available.

In the 59 municipalities, the total deaths from cholera were 3,200 or 1·5 per 1,000 of the population. The greatest sufferers were Vellore, Gudiyáttam, Salem, Kumbakónam, Vániyambádi, Tiruppattúr, Máyavaram, Tinnevelly, Karúr and Ṭrichinopoly. All evidence received continues to point to the usually accepted fact that water contaminated with the specific germ is the chief method of local propagation of the disease. For example, the District Medical Officer, Salem (Captain Gabbett), states :—

> Cholera has been as usual widely prevalent in the district. The disease was prevailing in an epidemic form in the Atúr taluk from February to April and October to December, in Tiruchengode taluk from January to May, Salem and Tiruppattúr taluks from February to May, in the Námakkal taluk January to March, Krishnagiri taluk during August, Uttankarai taluk during October, and in the Municipal towns of Vániyambádi and Salem during January and February to April, respectively, causing in all 5,568 deaths in the district. The worst outbreaks are invariably in taluks where the population are chiefly dependent by necessity or choice on river water for drinking. The most typical instance of this occurred in the Atúr taluk. Every village along the banks of the river which runs the length of the taluk was affected. In addition to the civil apothecary and hospital assistant already in the taluk, two hospital assistants were sent there on special cholera duty. It was an impossible task to prevent use of the infected river water or its constant re-infection, and other measures where of little avail. In villages and towns dependent on well water-supply, cholera outbreaks have often been promptly checked by closing the infected well and preventing infection of other wells by appointing caste waterman and guards.

Medical officers continue to report favourably upon the use of permanganate of potash in specifically contaminated water sources, but point out that it is impossible to give definite statements, as disinfection of the water-supply often results in other sources being employed by the people.

Small-pox.—There was 16,991 deaths from small-pox. Of these, the largest numbers occurred in South Arcot (2,540 or 1·2 per 1,000 of the population), Madura (1,947, or 0·9 per 1,000 of the population), Gódávari (1,829, or 0·9 per 1,000 of the population), Tanjore (1,825, or 0·8 per 1,000 of the population), North Arcot (1,550, or 0·7 per 1,000 of the population). In regard to these figures it must be remembered that vaccination is not compulsory in rural areas, and although a large section of the population appreciates its benefits, there is still some repugnance in submitting to the operation. Even where the mothers have no objection to the operation, it is difficult to convince them that infants under one year of age can successfully bear the operation. Hence, the risk to infantile life is considerable, more especially as a Hindu mother considers it necessary to show respect to the goddess of small-pox by joining in assemblies in crowded rooms, where, in the presence of the small-pox patient, ceremonies are performed to the deity. Re-vaccination, which, as the population emerges from being but a partially protected to being a fairly protected population, must become of greater importance, is rendered difficult in advance by it being conceived that small-pox is a disease of infancy, from which the adult has little real cause to protect himself, a conviction obviously of the same origin as the

European estimate of measles, namely, that infection spares not the child but passes over the adult, who, it is apt to be forgotten, has usually acquired immunity consequent upon an attack of the disease in infancy.

The appearance of small-pox in a locality is at once followed by special vaccinators being deputed to the spot, but, unfortunately, it does not follow in certain areas that their services will be utilized by the people, as a distinct prejudice against vaccination being conducted in epidemics is often met with. Disinfection of infected houses and clothing is also employed. Much prejudice was encountered in the preceding year against vaccination, the people having hopelessly confused the operation of inoculation against plague with that against small-pox; or, put in other words, an opinion existed that plague was being spread amongst the people by inoculation under the guise of vaccination. Happily, what at one time threatened to be a serious cause of retardation of vaccination has now subsided, as a result of common sense prevailing over the hysteria of panic.

On the total municipal population, the incidence of small-pox was 0·2 per 1,000 against 0·5 in rural areas, a difference which must, in consideration of the more crowded state of the urban areas, be ascribed to the better conduct of vaccination within them. In no instance did the total number of cases in any town exceed 45, except in Madura where the number was 73. Madura, Dindigul, Cuddalore, Chidambaram, and Tanjore, were those which chiefly suffered.

Fevers.—The total deaths from fevers were 245,549, or at the rate of 7·3 per 1,000 of the total population. This is the smallest rate recorded since 1883. It unfortunately cannot be asssumed that this is due to any striking measures taken for the reduction of malaria. Quinine has been successfully issued at post offices, and there have not been wanting those who have hunted the *anopheles;** but no great measures that would effect removal of superfluous mosquitoes, or moisture that would encourage their existence, from large areas have yet been carried out. Rather must the reduction be regarded as due to the imperfect character of the north-east monsoon failing to bring with it the essential presence of moisture in the soil, and to the not insignificant influence of a desire on the part of those registering deaths to escape suspicion of a disease whose prominent symptom is fever, namely, plague. Although it is well known that the majority of these "fevers" are of malarial origin, doubtless phthisis, pneumonia, pleurisy, affections of the liver, and diseases generally where fever is the prominent symptom, are included under this rough head. Until more medical men of Western education can find it profitable to compete for private practice against hakims and vaithiyans, or all existing subordinate members of the Medical Service are utilized in some measure for supervision of registration results, it would be impossible to attempt to differentiate malaria and specific affections included under the widely general term "fevers." In the meantime, some effort is being made to secure a better approach to accuracy in municipalities. I have advised all municipalities as to the advantages that would accrue by causing their Registrars to undergo training at the hands of local medical officers, sufficient for them to understand the more prominent symptoms of common diseases, so that, where no medical certificate accompanies a declaration of death, it shall be possible to elicit from the person making it the probable nature of the disease.

There is no lack of instances in this Presidency where a locality in which mild fever has existed has been converted into a deadly malarious place, by introduction of superfluous water for irrigation puposes, and there are instances where limitation of irrigation has been followed with beneficial results, but none where extensive works of drainage have secured the admirable curative influence obtained in other countries. Hence, it was hoped that the proposal to introduce a sewerage system and sub-soil drainage in the notoriously malarious town of Cuddapah would have afforded an object lesson. Unfortunately, up to date, the whole question has been under intermittent consideration. It has at last been decided by the Sanitary Board to deal with one of the factors concerned in the obstruction to the sub-soil water-flow, namely, the Patha-Cuddapah tank. It was proposed that this should be completely breached. In lieu of this procedure, it has lately been suggested to cut a channel to tap the sub-soil water layer between the town and the tank. This will, in all probability, have considerable influence if properly conducted, but unfortunately it has been determined to make all further action depend upon results so acquired. As this mode but deals with one of the factors, it is improbable that any marked results will be secured, and thus will be lost an opportunity of demonstrating what can be effected in a malarious area by whole-hearted efforts.

* I have recently issued a circular calling the attention of Local bodies to the importance of concerting measures to circumvent the *anopheles* genus of mosquitoes.

During the year Major Grant, I.M.S., Professor of Hygiene, invited attention in his report as Assistant Physician, General Hospital, Madras, to the severe nature of malarious fevers found in Madras town. His opinion was combated by certain medical officers, who apparently would not even admit the malarious origin of Madras fevers. Unknown to Major Grant, I had drawn attention to the same facts in 1894, and in subsequent years, in reference to sub-soil water fluctuation in Madras. I relied not only upon the clinical symptoms, but upon the careful microscopical diagnosis made in indubitably Madras-bred cases by Lieutenant-Colonel Sturmer, I.M.S. Not only does malaria exist in Madras itself, but intense forms are to be found within seven miles of it at Ennore—a once favoured health resort in which disturbance of sub-soil and surface water was brought about by railway and canal configuration. In 1896 I spent several days here, and obtained ample microscopical evidence of the presence of the *plasmodium malariæ* in its various forms, in subjects who had indubitably acquired the disease locally. It must not, however, be considered that malaria is the sole cause of fever in Madras town. Typhoid fever is by no means uncommon. Phthisis and low forms of pneumonia are prevalent amongst the poorer classes. There are doubtless also hitherto unclassified fevers to be demonstrated by the observer of the future.

Dysentery and Diarrhœa.—The term "dysentery and diarrhœa" necessarily includes all catarrhal affections of the intestines; it is impossible to say to what extent true dysentery is really in evidence. The death-rate in the Presidency from this cause was the same as in the preceding year, namely, 0·9 per 1,000. The highest proportion of mortality for districts from this cause was, as usual (if the town of Madras be excluded), in Chingleput. It is presumed that, in addition to the usual causative agents of dysentery and diarrhœa, there exists in that district a favouring cause in the brackish water used by a considerable proportion of the population. December and January were the months that exhibited the greatest mortality under these heads.

The proportion of deaths from dysentery and diarrhœa in municipal towns greatly exceeds that reported in rural areas, the total average being 4·3 per 1,000 in the former against 0·7 per 1,000 in the latter case. The following shows in descending order the towns which have returned the largest mortality under this head:—Gudiyáttam (8·6), Nizianagram (8·4), Madras (7·9), Walajapet (7·7), Vizagapatam (7·6), Tuticorin (7·4), Chingleput (7·1), Coonoor (6·6), Máyavaram (6·1), Vániyambádi (5·9), Parlákimedi (5·7), Conjeeveram (5·5), Tiruvannámalai (5·3), and Periyakulam (5·2).

These are towns either where conservancy is defective, or in which the water-supply is open to contamination; frequently, these two defects are conjoined with a brackish condition of the water. Variations in the registered amount of dysentery and diarrhœa from year to year are brought about by the occurrence of cholera, when doubtless attempts are made to conceal the existence of this disease, or, more especially at the beginning and end of such epidemics, mistakes in diagnosis occur; but on the whole, from year to year, there is, broadly speaking, little material change of the death-rates from dysentery and diarrhœa in any special town. There is little tendency to epidemic outbreak. On the contrary, where bowel affections have established themselves, they seem to claim their victims at fairly regular rates from year to year, proving that permanent not passing sanitary defects are at work. For example, the following have been the rates in certain towns during the last five years:—

Towns.	1895.	1896.	1897.	1898.	1899.
Chingleput	...	...	4·4	6·8	7·1
Coonoor	3·9	7·9	7·2	6·3	6·6
Madras	4·9	5·3	4·5	7·5	7·9
Periyakulam	5·1	5·9	6·3	6·1	5·2
Tuticorin	6·3	6·1	4·0	9·3	7·4

Injuries.—The deaths from injuries in towns was in the same proportion as in rural areas, namely, 0·4 per 1,000. When the figure are calculated upon the estimated population, the rate is reduced to 0·3, which has for nine years past been the invariable resultant under this head. For every 100 females that died of injuries, there were 112·4 deaths in males under this head. For every 100 suicides by females, there were 82·2 by males. 2,036 deaths occurred from snakebite.

All other causes.—In districts, the proportion of deaths under "all other causes" was 10·1 per 1,000 against 18·4 in municipalities. It is possible that this increase in municipalities implies a certain amount of extra care in differentiating death causation.

Sanitary Works.

Municipalities.—As foreseen when writing my last Report, sanitary advance, as indicated by permanent engineering works capable of favourably influencing the health of municipal populations, has been greatly trammelled by the conditions of uncertainty attending plague prevalence. No public body knew whether its ordinary resources, and even its borrowing powers, would not be strained to the utmost on being called upon to repel attacks by plague. Hence the policy of Municipal Councils has been to retain a considerable balance in hand, which should be available to meet the exigencies of a plague epidemic. Consequently, in 1899, no sanitary engineering work of great importance was commenced. The water-supply system of Tirupati was completed in time for the great annual festival of the Brahma utchavam at Tirupati. Water-supply extensions in Tanjore and Conjeeveram were also completed during the year. The small results secured are necessarily very disappointing, but were inevitable. Even where for routine purposes allotments had been made, the general unwillingness to part with funds is exhibited in the small expenditure during the nine months of the official year. Thus, whilst in 1898 by the end of December, 53·8 per cent. of the total allotment had been spent, in 1899 it amounted to but 47·0 per cent. On the other hand, the total allotment was somewhat larger during 1899 than in 1898, this being £129,574 against £104,770.

The following statement shows the expenditure on sanitary improvements :—

	1898–99.			1899–1900.		
	Amount sanctioned.	Amount expended.	Rate per cent. of expenditure to total allotment.	Amount sanctioned.	Amount expended during the nine months ending December, 1899.	Rate per cent. of expenditure to total allotment.
	£	£		£	£	
For conservancy	47,216	45,310	95·9	57,694	32,652	56·6
For improvement of village or town sites.	16,723	14,862	88·8	16,127	11,633	72·1
For improvement of water-supply, cleansing, repairing, and construction of tanks and wells.	10,390	10,308	99·2	49,511	13,082	26·4
For sanitary arrangements during fairs and festivals.	970	937	96·6	2,104	504	23·9
For construction and repair of markets and slaughter-houses.	1,286	844	65·6	1,196	969	81·1
For other sanitary outlay ...	8,012	4,794	59·8	2,944	2,066	70·1
Total	84,597	77,055	91·08	129,576	60,906	47·0

In municipalities, the amount realized by the sale of night-soil and rubbish was £2,130. The utilization of night-soil by cultivators is undergoing an extension that must necessarily be gradual. For a certain period, caste prejudices stand in the way of night-soil being utilized even when presented in the form of inodorous poudrette. But, it is evident that when the ryot has an "object lesson" showing the excellent results on crops, these prejudices disappear. Hence, the price of night-soil in certain municipalities is undergoing from year to year increase. Curiously enough, when the ryot has really made up his mind to use night-soil, in certain localities, he insists upon having the raw material or nothing at all; he regards poudrette as a weakly manure. "Trenching" followed by the sowing of crops by the municipality concerned with the hope of affording ryots object lessons was conducted at Bellary, Erode, Anakápalle and Nagore. At Rajahmundry, splendid crops of Batavia oranges are raised in sandy soil that has been richly trenched. At Karúr, Rajahmundry, Tinnevelly and Negapatam sewage farming

was conducted with profit. At Kumbakónam, Bezwada, Vizagapatam, Vizianagram, biological purification (filtration) of sewage was employed so as to intercept crude sewage passing to unsuitable outlets, such as streams liable to be used for drinking water and tanks. At Guntúr and Vizagapatam, arrangements are in progress which will enable sewage farming to be conducted next year. At Tanjore, sewage farming continues under unsatisfactory conditions, that is, a large portion of the total amount available is allowed to flow to waste. The sanctioned scheme for its full utilization was in abeyance during the year, owing to the loan of Rs. 33,000 required by the municipality not being accepted in the open market. In Madras, farming with sewage continued to be financially successful; but the farms fail to use the total sewage diverted to them. I advised, in 1894, unsuccessfully, that this surplus sewage should be received on filter beds rather than be allowed to be discharged at undesirable points.

District Boards.—I have, in my successive Annual Reports, expressed the hope that each following year would see issued the revised District Boards Act that would enable the sanitary requirements of District Board areas to be considered more seriously than at present. But it has not yet been possible for Government to finally deal with this Act. It is, however, before a Committee at the present time. I trust the revised Act will give more power for sanitary administration, otherwise efforts towards advance must be slow in character and far from abiding. At the present time, the ambition of District Boards rises little above the maintenance of roads, and this they usually perform unsatisfactorily and therefore with bad economy.

Last year, the sanitary allotment for all District Boards under all heads amounted to the very poor contribution of 8·3 per cent. of their total income; in 1899, it decreased to 7·2 per cent. This implies an allotment per head of the population of 3·6 pies, or about one farthing in current exchange. The number of villages conserved fell from 444 to 256. Much of the economy effected in respect of these villages was due to the non-employment of sweepers who simply remove rubbish from the streets of the village, but, on account of caste prejudices, refuse to deal with fœcal matter. There can be no doubt that the collection of rubbish to the neglect of night-soil was incongruous, and employment of these men was in this sense not justifiable. But in no case have District Boards, in making these sweeping economies, endeavoured to replace the sweeper by the more useful scavenger, or to concentrate upon certain of the larger villages correctly organized staffs, so as to render both rubbish and night-soil conservancy effective. On the contrary, the change has been carried out solely with a view to economy. At the same time, it must be confessed that difficulty in obtaining a reserve for possible plague epidemic charges justified efforts as to economy, although sanitation seems to have fallen an easy prey. It can but be hoped that, with the advent of better times, District Boards will in the future again expand the number of conserved villages.

The following statement exhibits the expenditure on sanitation during the year :—

	1898-99.			1899-1900.		
	Amount sanctioned	Amount expended.	Rate per cent. of expenditure to total allotment.	Amount santioned.	Amount expended during the nine months ending December, 1899.	Rate per cent. of expenditure to total allotment.
	£	£		£	£	
For conservancy	23,228	20,504	88·3	22,533	17,260	76·6
For improvement of village or town sites.	4,718	2,854	60·0	4,309	2,764	64·1
For improvement of water-supply, cleansing, repairing, and construction of tanks and wells.	8,742	5,728	65·5	7,065	3,372	47·7
For sanitary arrangements during fairs and festivals.	1,120	902	80·5	1,301	630	48·4
For construction and repair of markets and slaughter-houses.	3,933	3,089	78·5	4,200	1,193	28·4
For other sanitary outlay	2,246	1,141	51·2	1,996	578	28·9
Total	43,987	34,218	77·8	41,404	25,797	62·3

Fifteen Certificated Sanitary Inspectors were permanently employed by District Boards for routine sanitary duty, being an increase of three over last year. Having regard to the fact that District Boards have charge of a united area of 124,914 square miles containing a population of 32,603,685, and collect yearly an income of *£524,826, it must be said that their efforts towards organizing efficient sanitary staffs are exceedingly feeble. In the majority of districts, the early recognition of epidemic diseases and their prompt eradication are not matters that receive much attention. It is recognized that when an epidemic becomes obtrusive, it is necessary to do something. This is usually confined to temporarily detaching a solitary Hospital Assistant for charge of an area larger than an English county, and expecting him to divide his attention successfully between preventive and curative medicine. At the very least, there should be permanently appointed for one taluk—usually representing an average of 762 square miles—a single Certificated Sanitary Inspector, and there cannot be the slightest doubt that this could be easily afforded by every District Board in the Presidency. It also seems to me that there are important functions that require fulfilment, and sufficient funds available to enable *Assistant* Certificated Sanitary Inspectors to be employed in many of the unions.

Personal Proceedings and General Remarks.

I returned on the 3rd January 1899 from inspecting the plague-infected localities in the Alúr and Gooty taluks, on which duty I had been engaged during December of the preceding year. On the 7th of the same month I proceeded to Bellary with the object of opening a class for Temporary Sanitary Inspectors. This was an urgent necessity, owing to the impossibility of keeping pace with the demand for Certificated Sanitary Inspectors. Bellary was selected as the centre for training, with the hope of securing a preponderance of Telugu-speaking candidates—the plague-infected tracts being at that time chiefly where Telugu is the vernacular. The endeavour was to train well-educated men so as to be capable of recognizing the disease, of taking necessary preliminary action, and of understanding the methods and reasons for disinfection. The course of theoretical and practical instruction and examination extended from the 9th to the 27th January. Sixty extra Sanitary Inspectors were thus rendered available to meet possible urgent demands. Whilst in Bellary, the measures undertaken by the municipality against invasion were carefully entered into—especially with reference to the danger of importation from Hospet. In company with the Collector, plague arrangements at Hospet were duly inspected. During February, I inspected the Railway Inspection plague camp at Jalarpet. As the disease had appeared in Vellore, I made a complete inspection of arrangements and advised thereon. From thence, I proceeded to Arcot, and ascertained and advised as to methods there being adopted against plague. This tour occupied ten days. On the 21st February I started for Tirupati. As a pilgrim centre it was imminently liable to infection, and, indeed, imported cases had already appeared. The town was inspected. The plague-infected villages of Walajah, Pinji, and Ránipéttai, were then examined in company with the officers locally responsible. This tour occupied from 21st February to 5th March. During April the town of Cuddapah was inspected more especially with reference to the condition of the water-supply. By this time, plague had markedly declined. During the remainder of April and May I remained at head-quarters for the teaching of practical hygiene to candidates for the post of Certificated Sanitary Inspectors, and subsequently, as Chairman of the Government Technical examinations in Sanitary Science, undertook my part in their examinations. This is no part of my official duties, but the period spent consorts well with the fact that it is desirable to remain at head-quarters for the compilation of the Annual Administration Report. On the 7th June I proceeded to Guntúr and inspected the site for the proposed water-works. From thence I went to Masulipatam and conducted an inspection of the town. The municipality of Rajahmundry and the Union of Amalapuram were then inspected. In these places, which are notorious for beri-beri, the question of the existence of the disease amongst the populations was entered into, and numerous cases were examined clinically and microscopically. I returned to head-quarters on the 6th July. On the 18th July, I proceeded to Kurnool to undertake inspection of that town. With reference to the sanitary protection of the water-supply of this place, it was also necessary for me to examine certain villages along

* This is the actual annual average of the receipts for the five years ending 1898-99.

the Kurnool-Cuddapah canal. I returned to head-quarters on the 6th of August. On the 9th of August I was required to meet the Sanitary Board, which was convened to discuss on the spot the water-supply scheme of Coonoor. I took the opportunity of making an inspection of the town. In response to a request by the Ootacamund Municipality, I consulted with its Committee as to the proposed drainage scheme. The opportunity was also taken of inspecting Ootacamund, and special care was exercised in attempting to ascertain the ordinary methods of spread of typhoid fever in that health-resort. I remained at head-quarters till the 3rd of October. On the 5th October I journeyed to Vizianagram, where the District Medical and Sanitary Officer (Captain Giffard, I.M.S.) had reported an interesting outbreak of beri-beri amongst the Native Infantry. A number of cases were examined by me with the aid of the District Medical and Sanitary Officer and the officer in charge of the Regiment. The Municipal town of Vizianagram was now inspected. I returned to Madras on the 13th October. I then proceeded to Tiruvannámalai, with special reference to the then approaching great annual festival. I returned to Madras on the 20th October. From the 4th to 27th November I was absent from head-quarters, and during this period I inspected Trichinopoly, Srírangam, Madura, and Tanjore. Dindigul was visited with special reference to the water-supply scheme. I again left Madras on the 9th December with the intention of making a tour throughout the West Coast municipalities. I arrived at Calicut and inspected a portion of the town on the 10th. On the 11th I received a telegram reporting an alarming outbreak of plague at Tiruppattúr in the Salem district. I at once proceeded there, and, having consulted with the Collector, returned to Calicut on the 15th. I was on that date attacked with an illness that incapacitated me from conducting any further out-door work, although my office work continued to received my full attention. Written reports of the above inspections were forwarded in each case to the authorities concerned and to Government. During the year, a distance of 6,749 miles was travelled by road, rail, and canal.

The total attacks of plague in the Presidency for the whole year amounted to 2,385 followed by 1,843 deaths. By the middle of May, the plague epidemic which had commenced in the last quarter of the previous year in the Deccan districts of Anantapur, Bellary and Kurnool showed marked symptoms of diminution in March, and had completely disappeared within the first three weeks of May. In these districts there had occurred a total of 70 imported and 716 indigenous cases followed by 56 and 588 deaths, respectively. In the North Arcot district plague lingered up to a later date; indigenous cases did not cease till the end of June. In this district there were 67 imported and 647 indigenous cases, followed by 55 and 501 deaths, respectively. In the Hosúr taluk of the Salem district, however, although from May to June there was exhibited a decrease of indigenous cases, plague manifested a continued, though not severe, prevalence throughout the year. In December a second taluk in the Salem district was attacked. This followed a severe outbreak in the municipal town of Tiruppattúr, owing to a lamentable want of discretion by the municipal authorities. The total imported cases in this district were 141 and indigenous cases 682, followed by 88 and 508 deaths, respectively. Kollegal taluk of Coimbatore was subjected to a short epidemic outbreak extending from October 7th to December 16th. In this district there were 1 imported and 47 indigenous cases, followed by 37 deaths. Imported cases were also reported in Chingleput, Nilgiris, Trichinopoly, Nellore and Madras town. In none of these instances was importation followed by indigenous plague.

Having regard to the usual behavour of plague, as reported by various authorities, affecting recrudescence of the disease in villages where it had appeared in its indigenous form, it was felt the chances were considerable that, either following the moisture incident to the south-west monsoon, the decreased incidence shown in April and May would give way to fresh outbreaks, or that at least on the expiration of a year, which would repeat the same meteorological influences under which it had flourished, a recurrence would take place. I am glad to say, however, that so far in this Presidency not a single instance has been recorded of what would be correctly understood as recrudescence. Indeed, were it not for the continued presence of plague in the Hosúr taluk of the Salem district—a condition that may well be ascribed to the free intercourse which exists with the neighbouring infected Mysorean villages—it might be said that villages that have been once affected have escaped fully any recurrence. The deduction might be drawn that sources of infection had been so carefully sought for and destroyed that no recrudescence was possible. It seems to me, however, that the chances are that when it is implied by recrudescence that the disease had completely disappeared from human beings and that

the germ, with decreased vitality, but awaited favouring conditions in some suitable medium for a return to virulence and spread to human beings, there is assumed more than were it be held that it was due to the continued propagation of the disease by its slight and, therefore, unrecognized existence amongst the population.

It cannot be said that additional information as to transmission of plague has been gained. The opportunities for observation have been chiefly in the hands of non-professional persons, owing to the peculiar constitution of plague staffs incident to the policy pursued throughout India. Where medical men have been employed, it is rarely they have had sufficient time at their disposal to correctly elucidate occurrences. In my last year's report, I held that the great importer of plague was the human being, and that, subsequently, in the affected areas its spread was facilitated by rats, and particularly drew attention to the absence of evidence implicating inanimate articles imported from a plague-infected area as the original cause of plague in a hitherto unaffected locality. The experience of both lay and medical officers in the Hosúr taluk of the Salem district, however, dictates that not only rats but grain infected by them is an important mode of spread. Indeed, the District Medical and Sanitary Officer considers infection by mouth by medium of infected food to be indubitably the chief mode of spread. Unfortunately, the evidence which he brings forward, although giving colour to his assertion, does not seem to be of a nature that could be accepted with the certainty necessary in dealing with so important a statement. It is, however, necessary to collect all facts bearing on the question of mode of transmission with care, and with the object of inducing officers to collect further data, I draw attention to this officer's opinion. With a hope that in each district invaded it would be possible gradually to collect a store of facts that would illustrate the truth in such matters, the Plague Commissioner under my advice, in his Proceedings No. 951, dated 12th April, 1899, required that 'Collectors of Districts should maintain a special record in diary form, to which all persons under their orders dealing with plague should be requested to contribute facts coming under their own observation of a sanitary nature. Unfortunately, no Collector has maintained the record suggested.

There was no change of policy with which Government met the requirements of plague administration during the year. The method of detection trusted to has been that of inspecting travellers by road, rail and sea on routes communicating with infected areas, isolation of the sick, and requiring the healthy during the periods of possible incubation to be subject to surveillance whilst in no way restricting their movements. The District Board, municipal and village organizations lend themselves to the successful effecting of this scheme. In one respect a flaw existed in the arrangements, in that it was possible for persons from affected villages to scatter hither and thither before coming under the influence of the passport regulations. Hence a new regulation was required. It has been arranged that *before* starting from an infected village the inhabitant should obtain a passport which, under the usual rules, will secure his surveillance whilst travelling beyond its limits. It is also required that inhabitants of an infected village proceeding to camp in its neighbourhood should receive the approval of the plague officer of the site selected by them, in token of which "passes" were to be issued. A system which demands that at certain points an uneducated native should be given a piece of paper, by which it is required he should present himself for a period of ten days to the Plague authority at any village or town at which he may halt, may seem well-nigh visionary; yet, experience shows that, under this simple method, the free population can be allowed to pass from one end of the Presidency to the other, with fair assurance that both the passport bearer and the local officer responsible for the examination of his health will fulfil their duties. By means of this system, a large number of the imported cases have been detected at the very onset of the disease, and thus the possibility of spread has been enormously minimized. Of course, it has not been possible to ensure that all passport-holders should have been put under surveillance; still, the amount of success which has attended the endeavour suffices to prove its great utility—more especially when contrasted with the inconvenience and indifferent results brought about in at least one other Presidency, by the adoption for a considerable period of the principle of "detention camps"—land quarantine. In my last year's report, I quoted the percentages of failure to trace the passport-holders as ascertained in the districts. As I have no doubt vigilance has not been relaxed I have not thought it necessary to put Collectors to the trouble of furnishing me again with statistics. A fair example, however, of what can be done, even in large towns, is illustrated by results obtained in the Municipality of Madras where, failure to trace passport holders occurred only in 3·4 per cent. of 55,407 cases. Discipline, therefore, in a free population cannot be

absolutely complete, and it must be admitted that introduction of plague is possible by cases that have eluded surveillance; yet, the figures are so enormously in favour of successful surveillance that no one can feel otherwise than that the system is of distinct practical value.

In towns, much passive opposition to evacuation of infected houses has been exhibited; but, in rural areas, the benefit of rapid evacuation is often so well recognised that on the occurrence of plague there is a general exodus to encampments on clean sites outside the town. Lieutenant-Colonel Lawrie, I.M.S., having adversely criticised the bacterial purity of haffkinine before the Plague Commission, the educated native public lost faith in anti-plague inoculation. As a result only 5,955 persons were inoculated during the year. It will take some time before the prejudice thus caused can be eradicated.

The use of Chinese pumps was found in practice arduous to the men employed; hence, I designed a so-called "gravitation disinfector," which has been favourably reported upon by medical officers who have seen it in use. This consists of a twenty-four-gallon bucket mounted on a platform on wheels fitted with guiding rods, which permit of the bucket being elevated to a height of 20 feet. To the bucket is attached a canvas hose pipe 120 feet long having a suitable spray at the end. Two men can transport and place the machine in a position outside the house to be disinfected. A powerful spray of about 18 feet in height can then be secured, and be conducted to any part of the interior with ease. With the aid of Mr. Phipps, of the Madras Railway Company, in carrying the idea into practice, I also initiated a disinfecting machine that would apply a hot gas blast to any part of indestructible floors and walls—much on the principle of the painter's lamp. On comparing bacteriologically results of disinfection of floors by this machine with those secured by other observers with the acid solution of the perchloride of mercury, I came to the conclusion that, so far as superficial layers of earth are concerned, the use of heat presents no advantage over that of the disinfectant named, whilst the consumption of time in securing the necessary temperature in so badly conducting a medium as earth, inevitably charged with more or less moisture, was to its disadvantage, unless it be proved that the plague microbe could exist at greater depths than readily reached by soakage of a fluid disinfectant, say, one-sixth of an inch—as to which, Yersin notwithstanding, information is incomplete.

I have already stated the area of the Presidency examined by me with reference to beri-beri. This interesting work I undertook more especially with the object of ascertaining how far it is possible to accept the contention by Captain Fearnside, I.M.S., in a pamphlet which was communicated to a professional journal and to the Government of India, that the symptoms usually recognized in this Presidency as beri-beri are due to a malignant infective form of the *plasmodium malariae*. I made no further advance than dozens of observers better fitted for the task in ascertaining what is precisely the nature of the specific germ of beri-beri, but of this I feel absolutely convinced, after examining microscopically the blood of a large number of cases, that the disease known as beri-beri in the Madras Presidency is not due to the presence of the *plasmodium malariae*. That beri-beri and malarial cachexia may co-exist there can, of course, be not the slighest doubt; and, when they do co-exist, the condition of the patient is greatly aggravated. But this is a very different matter to malaria being regarded as the *fons et origo* of the disease.

Members of public bodies are rarely open to conviction as to contamination of the sub-soil in connection with water-supplies. The great distances from possible sources of contamination and the actual points of withdrawal of water-supplies tend to make them believe in safety from any form of contamination, when guarded by the well-known purifying influence of filtration through the sub-soil. To be able to easily demonstrate to unbelievers the source of contamination is important. The use of common salt or salts of lithium renders necessary a preliminary as well as subsequent analysis of water, involving expenditure of time and trouble. Hence, it is worth while placing on record how readily a demonstration is procurable by utilizing "fluorescence." In an experiment conducted by me at the Cuddapah water-works, it was easily proved that when the line of saturation in the infiltration bed was lowered by pumping, there occurred an inrush of possibly contaminated water from a neighbouring road ditch, and, further, that contamination so acquired passed through the sub-soil so as to reach wells 303 yards distant. When it is remembered that this is a mere visual test, its advantages over older methods are obvious. It has been employed in America for the purpose indicated for some time past.

I have already referred (page 162) to the increasing interest which is taken in the subject of sewage filtration. The principles followed by me were such as advocated by the Massachusetts State Board of Health. These, in my opinion, serve admirably when applied

to designs of filters where supervision is likely to be of the smallest. At any rate, these principles suffice for what I term "makeshift filters," that is, filters devoid of valves and other arrangements which would be necessary adjuncts of Dibdin's mode. A clay lined earthen reservoir with sand, washed gravel, and road metal under-drained by tile drains offer cheap and efficient media.

When such filters are worked intermittently so as to secure aeration, I think it will be rarely that any more elaborate modes need be adopted in this country. The utility of the "septic tank" is a matter which has apparently "caught on" to the mind of the educated public of India. Very little consideration will, however, show that the reasons for the success of this and of Dibdin's method in Great Britain depend upon conditions that are not likely to occur frequently in India. The bugbear of a Municipal body in disposing of its sewage in England is the great cost of land, prohibiting disposal of sludge and fluid sewage. In India, however, it can be but rarely that the municipality need fear the cost of land for what is proved to be in Madras, at least, the profitable investment of sewage farming. Where a town has a correctly designed system of sewerage, then I hold that usually disposal by sewage farming, or highly under-drained beds will prove ample for requirements in India, and I foresee that the great utility of sewage filtration is where but imperfect systems of sewerage exist. Judiciously placed sewage filters will then prove of the utmost value in preventing reckless contamination of water sources. Similarly, in the absence of sewerage systems, filtration of sewage at the household—permitting the filtrate to flow on the surface—will prove an infinitely safer method than consigning it to the sub-soil by medium of leaky cesspools. Both public and private sewage filters have been in use since 1895 in this Presidency.

Since 1891, when I was placed on "special duty" by the Madras Government with reference to ascertaining the best mode of supplying preserved animal lymph, I have from time to time urged the importance of this Presidency possessing a Central Vaccine Institute, where animal lymph should undergo cultivation and preservation under conditions that would guarantee the requisite absolute cleanliness and high grade of activity. I have also advocated the advisability of uniting a bacteriological laboratory with this Institute, with the object of placing at the disposal of the bacteriologist the splendid opportunities of studying serum therapeutics, which the possession of a large number of animals and facilities for their handling and care would afford. It is with no small pleasure, therefore, that I find myself able to record that Government has now consented to the establishment of such an institute.

Sanitary Engineering.

The extension of the water-works at Conjeeveram, which was in progress in 1898, was completed in the year under review, as also the extension of the pipe lines in Tanjore. These two works were carried out under the supervision of the Sanitary Engineer. The scheme for the water-supply of Tirupati at an estimated cost of £15,400, which was undertaken by the Public Works Department, was also completed during the year.

Three municipal towns were surveyed in connection with water-supply, and two drainage and seven water-supply schemes were prepared and submitted either to the Sanitary Board or to Government. The schemes for the water-supply of Tuticorin and Coonoor, and for the extension of the water-works at Trichinopoly and Cuddapah, were sanctioned by Government—the first two for execution by the Public Works Department and the remainder by the Sanitary Engineer. A scheme for the extension of the pipe lines in Kurnool was also sanctioned during the year, but the execution of the work was not insisted upon, owing to the crippled state of the finances of the municipality. The Inspector of Steam-boilers and Prime-movers visited the pumping stations of the water-works at Kurnool, Conjeeveram, Cuddapah, Madura, Trichinopoly, Tanjore and Dindigul, and reported on the engines, boilers and pumps. The condition of the pumping plants is stated to have much improved since their examination by this officer in 1897. The Sanitary Engineer prepared six type designs for sanitary works and gave advice to the Sanitary Board in 57 cases.

Sanitary Board.—The constitution of the Sanitary Board continued to be the same as in the previous year; but the rules for the conduct of its business were slightly modified

so as to permit a local board or municipal council or other authority to apply to Government for orders in the proper department when it objects for financial or other reasons to adopt a design or an estimate prescribed by the Sanitary Board. The Board scrutinised plans and estimates for one Provincial, 34 Municipal and 79 Local Fund works of the estimated cost of £128,876. These comprised schemes for the water-supply of Tuticorin, Guntúr, Periyakulam and Bezwada, for the extension of the water-works at Trichinopoly and for the drainage of the Ootacamund bazaar, which were examined and laid before Government. Proposals for 17 other schemes were also considered by the Board, although estimates for them had not been prepared. Six new type designs were approved for issue, but as many of the designs already issued have been found too expensive for the minor local bodies, the Board has taken steps for the preparation of cheaper designs.

ABSTRACT OF REPORT OF THE SANITARY COMMISSIONER FOR BOMBAY FOR 1899.

(*Lieutenant-Colonel J. W. Clarkson, I.M.S.*)

General Population.

European and Eurasian Vital Statistics.

The European civil census population of 1891 in the Bombay Presidency, exclusive of cantonments in quasi-foreign territory, is 18,486. During the year 1899, 221 births and 231 deaths were recorded against 246 and 243 in 1898—a birth-rate of 11·96 per 1,000 against 13·31 in 1898 and a death-rate of 12·52 against 13·14. By sexes 116 males and 105 females were born against 141 and 105 in 1898, and, as regards deaths, 145 males and 86 females died against 145 and 98 in 1898.

The Eurasian census population of 1891 is 8,519. During the year 1899 the births amounted to 166 against 123 in 1898 and the deaths to 185 against 169, the rates being 19·49 per 1,000 against 14·44 in 1898 and 21·72 against 19·84. Of those born, 82 were males and 84 females against 64 and 59 in 1898; as regards deaths, 95 males and 90 females died against 93 and 76 in 1898.

The causes from which deaths among Europeans and Eurasians were recorded are given in the following table:—

Causes of deaths.		Europeans.				Eurasians.			
		1899.		1898.		1899.		1898.	
		Number of deaths.	Ratio per 1,000 of population.	Number of deaths.	Ratio per 1,000 of population.	Number of deaths.	Ratio per 1,000 of population.	Number of deaths.	Ratio per 1,000 of population.

	Total ...	3	*	4	*	—	—	3	*

* As the population for the cantonments in quasi-foreign territory is not obtainable, the ratio of deaths cannot be worked out.

Two deaths from cholera among Europeans were recorded during the year 1899, of which one took place at Dhárwár and one at Ahmedabad. In 1898 no deaths from this disease were recorded among Europeans. Among Eurasians no deaths from cholera were recorded in 1899. From small-pox there was only one death in the City of Bombay and that occurred in an Eurasian.

In the City of Bombay during the year 1899 there were among Europeans 12 deaths recorded from plague against 13 in 1898. In the collectorate of Poona and Dhárwár

there were among Europeans three and one deaths, respectively, due to plague. Among Eurasians there were 32 deaths recorded from plague, of which 29 took place in the City of Bombay, one in the collectorate of Ahmednagar and two in Poona. In 1898 there were 23 deaths recorded, 22 in the City of Bombay and one in the collectorate of Poona.

Native Population— Vital Statistics.

Births.—In the Presidency of Bombay, including Sind, during the year 1899, there were 685,348 births registered against 582,371 in 1898. The recorded births for the year under report were more by 102,977 than the number registered in the previous year, and also more by 37,574 than the decennial mean ending 1898. By sexes there were 355,869 males and 329,479 females against 302,635 and 279,736 in 1898.

The following table shows the number of births registered in each year from 1889 to 1899, their ratios per 1,000, and the proportion of males to females :—

Years.	Population.	Number of Births registered.			Ratio per 1,000 of Population.			In every 100 Births there were		For every 100 Male Births the Females were
		Males.	Females.	Children.	Males.	Females.	Children.	Males.	Females.	
1889	16,454,414	312,974	287,515	900,486	19·02	17·47	36·49	52·12	47·88	91·87
1890	16,454,414	333,698	307,417	641,115	20·28	18·68	38·97	52·05	47·95	92·14
1891	18,820,346	354,630	328,047	682,677	18·84	17·43	36·27	51·95	48·05	92·50
1892	18,820,346	337,150	313,517	650,667	17·91	16·66	34·57	51·82	48·18	92·99
1893	18,820,346	345,424	318,881	664,305	18·35	16·94	35·30	52·00	48·00	92·32
1894	18,820,346	342,911	317,357	660,268	18·22	16·86	35·08	51·94	48·06	92·55
1895	18,820,346	350,115	324,189	674,304	18·60	17·23	35·83	51·92	48·08	92·59
1896	18,820,346	359,097	332,750	691,847	19·08	17·68	36·76	51·90	48·10	92·66
1897	18,820,346	327,573	302,120	629,693	17·41	16·05	33·46	52·02	47·98	92·23
1898	18,820,346	302,635	279,736	582,371	16·08	14·86	30·94	51·97	48·03	92·43
Mean for 10 yrs.	18,547,160	336,621	311,153	647,774	18·35	16·96	35·31	51·97	48·03	92·43
1899	18,820,346	355,869	329,479	685,348	18·91	17·51	36·42	51·93	48·07	92·58

The recorded birth-rate for the year was 36·42 per 1,000 against 30·94 in 1898, and a decennial mean of 35·31.

The number of births recorded was higher than that in the previous year in all the five registration districts.

Of the 24 collectorates and districts the number of recorded births in 1899 was higher than in 1898 in all the collectorates except the City of Bombay, Panch Mahâls and the district of Thar and Párkar. The City of Bombay, as usual, recorded a low birth-rate, 12·88 per 1,000, against 13·08 and a decennial mean of 17·67, and it was owing to plague. As regards the low birth-rate in the district of Thar and Párkar the Deputy Sanitary Commissioner, Sind Registration District, remarks that owing to famine in this district and consequent emigration of the people into other parts of Sind, the birth-rate for the year for the district of Thar and Párkar was lower in 1899 than in 1898 and the decennial mean.

The recorded birth-rates among the urban and rural populations of the Presidency were 26·48 and 37·80 against 24·05 and 31·91 in 1898. Except in the collectorates of

Ratnágiri, Kánara, Kaira, and throughout Sind, with the exception of Upper Sind Frontier, the birth-rates were higher among the rural than in the urban population. The urban rates were in many places greatly affected by the exodus caused by plague.

Out of 56 towns in the Presidency, 21 had a birth-rate exceeding 40 per 1,000. Poona, Belgaum, Bombay, Alibag, Ahmednagar, Dhárwár and Panvel have very low birth-rates. This, in the case of Poona, Belgaum and Bombay is chiefly due to the decrease in population owing to the exodus caused by plague.

Deaths.—Among the civil population in the rural, town, and cantonment circles in the Presidency, 672,269 deaths were registered during the year 1899. In 1898, 548,825 deaths, or 123,444 less than in 1899, were recorded.

The following statement shows the number of deaths recorded in each year since 1889 :—

1889	...	518,562	1893	...	511,831	1897	...	749,916
1890	...	463,616	1894	...	607,179	1898	...	548,825
1891	...	513,132	1895	...	538,540	1899	...	672,269
1892	...	611,742	1896	...	596,472			

Of the total deaths registered, 355,241 occurred among males and 317,019 among females (the sexes of 9 deaths in Sind could not be ascertained), against 288,796 and 260,029 respectively, in 1898. The death-rate per 1,000 in 1899 was 35·72 against 29·16 in 1898 and a decennial mean of 30·85. The millesimal rates of males dying to males living was 36·48 , and of females dying to females living was 34·90. In 1898 these ratios were, respectively, 29·66 and 28·63. For every 100 females who died, 112·06 deaths among males were recorded, but these proportions vary considerably in the following collectorates and districts :—

In Khándesh the ratio of male to female deaths was			113·15 per cent.
„ Thána	do.	do.	114·81 „
„ the City of Bombay	do.	do.	144·18 „
„ Kaira	do.	do.	114·48 „
„ Karáchi	do.	do.	125·11 „
„ Hyderabad	do.	do.	125·27 „
„ Thar and Párkar	do.	do.	129·24 „
„ Upper Sind Frontier	do.	do.	121·02 „

The highest death-rate occurred in the Western Registration District (45·57), which had suffered to a considerable extent from plague ; the lowest death-rate was in Sind (19·59). The death-rates in 1899 were higher than the decennial mean in all the registration districts except Sind.

The Deputy Sanitary Commissioner, Gujarát Registration District, remarks that "notwithstanding the ravages of plague, more or less severe throughout Gujárát during the past three years, and the effects of famine, which began to be appreciable during the last three months of the year, the general survey of births and deaths presents a satisfactory record." He further adds that "there is an almost complete absence of the usual scourges, small-pox and cholera, while the death-rate, in spite of plague and famine, is only slightly above the average of the past ten years.

The recorded death-rate per 1,000 in 1899 was higher than in 1898 in all the collectorates and districts except the collectorates of Dhárwár, Shikárpur and the district of Upper Sind Frontier. The Upper Sind Frontier was free from plague and scarcity. The high mortality in the City of Bombay and in the collectorates of Ahmednagar, Poona, Sholápur, Sátára, Belgaum and Dhárwár was due to plague.

The Deputy Sanitary Commissioner, Central Registration District, states that "there was practically no cholera and the deaths from small-pox were low, but there was a very heavy mortality from plague, and this accounts for the high death-rate during the year."

The Deputy Sanitary Commissioner, Southern Registration District, remarks that amongst the cause of deaths, fever and plague form the largest items in the Belgaum and Dhárwár Collectorates.

Deaths by sexes.—In the City of Bombay and the Upper Sind Frontier, the recorded death-rates of females were higher than those among males. In Sátára, Karáchi and Shikápur, the death-rates of males and females were about equal. In the remaining collectorates the death-rates of males exceeded those of females. In 1898 the female death-rates exceeded those among males in the City of Bombay, Broach, Kaira, Panch Maháls, Thar and Párkar and Shikápur.

Deaths by ages.—The figures given below show the total deaths in 1899 under different ages, as also the ratios per 1,000 living, calculated on the population of each age-period enumerated at the Census of 1891 and the percentage of total deaths :—

Age-period.	Population according to Census of 1891.	Number of deaths.	Ratio per 1,000 of population.	Percentage on total deaths.
Under 1 year	680,472	134,036	196·97	19·94
1 and under 5 years	2,178,646	104,459	47·95	15·54
5 and under 10 do.	2,615,588	38,030	14·54	5·66
10 do. 15 do.	1,820,754	28,373	15·58	4·22
15 do. 20 do.	1,470,976	23,697	16·11	3·52
20 do. 30 do.	3,410,817	66,488	19·49	9·89
30 do. 40 do.	2,765,949	67,400	24·38	10·03
40 do. 50 do.	1,841,976	56,032	30·42	8·33
50 do. 60 do.	1,117,120	52,013	46·56	7·74
60 and upwards	918,048	101,741	110·82	15·13
Total	18,820,346	672,269	35·72	100·

As compared with last year, the table shows that there has, in the present year, been an increase in the percentage of deaths under 5 years, and a decrease between 20 and 60. The Deputy Sanitary Commissioner, Sind Registration District, remarks that "owing to the famine people have been selling their cows during the last 2 months of the year, lots of deaths have taken place from convulsions on account of bad feeding."

Deaths by causes.—The subjoined table shows the deaths in 1899 arranged according to the specified causes laid down by the Government of India, and contrasted with the results for 1898, and with the decennial mean. The "causes of death" will be briefly noticed in the next section :—

Causes of deaths.	Mean for 10 years, 1889–1898.		1898.		1899.	
	Number.	Ratio per 1,000 of population.	Number.	Ratio per 1,000 of population.	Number.	Ratio per 1,000 of population.
Cholera	25,459	1·39	4,368	·23	8,579	·46
Small-pox	3,540	·19	1,834	·10	1,946	·10
Plague	Not available.		86,191	4·58	96,596	5·13
Fevers	384,517	20·96	216,324	11·49	228,438	12·14
Dysentery and diarrhœa ...	43,918	2·39	56,789	3·02	74,736	3·97
Injuries	6,155	·34	6,984	·37	7,102	·38
Other causes	102,393	5·58	176,335	9·37	254,872	13·54
All causes	565,982	30·85	548,825	29·16	672,269	35·72

The year 1899 was very unhealthy as compared with the previous year. The death-rate in the latter part of the year commencing from August to the end of the year was increased by the effects of plague and scarcity.

The recorded death-rates among the urban and rural populations of the Presidency were, respectively, 64·10 and 31·76 per 1,000 of population against 47·88 and 26·55 in 1898. Among the rural population the death-rate was higher than in the urban population in the collectorate of Kánara, where the rural death-rate exceeded the urban by 10·20.

Chief Diseases.

Cholera.—During 1899 cholera caused 8,579 deaths throughout the Presidency or 4,211 more than in the preceding year. The epidemic was most prevalent in the Belgaum, Karáchi and Dhárwár Collectorates, where 4,474 or 4·42, 2,394 or 4·27 and 1,335 or 1·27 deaths per 1,000 of population, respectively, took place ; whilst the minimum mortality occurred in the Ahmednagar and Sholápur Collectorates, in which there is only 1 death registered.

In December 1898 cholera deaths were reported from the collectorates of Belgaum and Dhárwár and the City of Bombay. In January of the year under report the disease was present only in the Belgaum Collectorate and in the City of Bombay, causing 10 deaths

in the former and 13 in the latter. In February 548 deaths were returned from 3 collectorates, namely, Belgaum, Dhárwár and Kánara and the City of Bombay. In March, however; in addition to the above, the collectorate of Karáchi was affected and 1,568 deaths were registered. In April the disease increased and caused 1,980 deaths. In May the disease had spread to 7 out of the 24 collectorates in the Presidency and 2,199 deaths were reported from them, the maximum for the year. In June and July the disease was prevailing in 6 collectorates and 1,389 deaths were reported. In August, September and October there was a decrease, 811 deaths having been reported. In November there were 33 deaths from this disease in 2 collectorates, and in December only 28 deaths.

In the Belgaum Collectorate the death-rate attained the high ratio of 4·42 per 1,000 of population. In the Karáchi Collectorate there was also a high ratio, namely, 4·27 per 1,000, whilst in the remaining collectorates the epidemic did not show high ratios.

By seasons 1,916 deaths out of 8,579 were recorded in the rainy season of 122 days.

Out of 220 rural circles or tálukas, 26 were affected by cholera, and out of 56 town circles, 12 were affected during the year. The affected area included 461 out of 25,143 villages in the Presidency. The highest percentage took place in Belgaum, where 259 villages out of 1,076, or 24·07 per cent., were affected. In Karáchi and Dhárwár Collectorates the percentages were 10·23 and 7·83 respectively.

Small-pox.—There were 1,946 deaths from small-pox (995 males and 951 females) against 1,834 in 1898, and a decennial mean of 3,540. The number of deaths during the year, though higher by 112 than the preceding year, was the lowest record with two exceptions during the last 12 years. The Western Registration District was the most affected, after it came the Southern and Central Registration Districts, Sind was very slightly affected, and the Gujarát Registration District gave only nine deaths. The ratio per 1,000 was 0·10, against 0·10 in 1898, and 0·19 the decennial mean. These figures may be considered very satisfactory, and they testify to the exceedingly good vaccination work which now for some years has been done in the Presidency. As regards collectorates, there was an increase in Thána, Bombay and Kolába in the Western, Ratnágiri in the Central, Bijápur in the Southern, Panch Maháls in Gujarát and Karáchi in Sind Registration Districts. The highest death-rate (0·56) occurred in Thána, and the lowest (0·01) in Belgaum and Shikárpur. The death-rates, 0·54 per 1,000 in the City of Bombay, and 0·46 in the collectorate of Kolába were much higher during the year 1899 than in 1898, 0·07 and nil, respectively. There was only one death from small-pox in the Hyderabad Collectorate, whilst in the collectorates of Surat, Broach, Kaira, Ahmedabad, and in the districts of Thar and Párkar and Upper Sind Frontier no deaths from small-pox were recorded.

According to age 28·37 per cent. of the small-pox deaths occurred amongst infants under one year of age, whilst 45·73 per cent. took place among children one to ten years, the remaining 25·90 being among persons over ten years of age.

Fever.—There were 228,438 deaths registered under the heading "Fever" (120,540 males and 107,898 females) against 216,324 in 1898, thus there was an increase of 12,114 deaths as compared with the previous year; the decennial mean is 384,517 which includes the deaths from plague for the past three years. The death-rate was 12·14 per 1,000 compared with 11·49 for the previous year and a decennial mean of 20·96, and this includes the deaths from plague during the years from 1896 to 1898. The death-rates in the Western and Central Registration Districts were higher during the year than that for 1898. In Sind the death-rate was nearly the same as that for 1898, and in the remaining districts it is lower than the previous year. In the collectorates of Khándesh, Násik, Thána, City of Bombay, Kolába, Ahmednagar, Poona, Sholápur, Surat, Ahmedabad, Hyderabad and the district of Thar and Párkar, there was an increase of ratios during the year over 1898. The collectorate of Broach heads the list with a very high ratio, 24·57 per 1,000, against 26·84 in 1898, and 32·53 in the previous ten-year mean. In the collectorates of Panch Maháls and Ahmedabad and in the districts of Thar and Párkar high ratios are observed, 21·44, 21·75 and 22·41 per 1,000, respectively.

Plague.—At the end of 1896 there had been a total of 2,909 attacks and 2,086 deaths deaths from plague, 61,093 attacks and 46,944 deaths were recorded during 1897, 110,369 attacks and 86,191 deaths were recorded during 1898, and 126,287 attacks and 96,596 deaths in 1899; the table below gives the progress of the disease by months in each collectorate for the year under report. The epidemic continued throughout the year, and was at its lowest intensity in June and reached its maximum in September. Only one district, Thar and Párkar, remained uninfected throughout the year.

174

Khándesh.—Plague prevailed to a limited extent up to March, after which it fell rapidly until June, and the district was free during the month of July, In August, however, it was again re-infected and continued so up to October, when five deaths were recorded that month, when it ceased. Twenty-two towns and villages were affected, and there were 782 attacks and 620 deaths reported.

Násik.—Was affected during the whole of the year. From January to June it was to a limited extent, but it suddenly rose from 130 deaths in June to 768 deaths in July, and continued increasing until the maximum was reached in September, when 2,976 deaths were recorded; it declined just as rapidly, and the minimum was recorded in December, viz., 27 deaths. 154 towns and villages were affected, and there were 10,791 attacks and 8,441 deaths reported.

Thána.—Was affected during the whole year as in 1898. In January the disease was on the increase, and this continued until March, when the maximum number of deaths, 970, took place, and then gradually declined until December, when 152 deaths were recorded. The total for the year was 146 towns and villages, 4,996 attacks and 4,362 deaths.

Bombay City.—As in 1898, the disease was prevailing throughout the year. The maximum deaths, 4,758, were reached in March, when it rapidly fell until June, giving 228 deaths the minimum, and then again there was a gradual rise, and continued so until the close of the year, when 994 deaths were recorded. The total for the year was 19,454 attacks and 15,874 deaths.

Kolába.—Plague prevailed to a very limited extent throughout the year, it gradually declined from January until September, when only one death was recorded; at the last month of the year there were 43 deaths. 80 villages were affected and there were 1,070 attacks and 902 deaths reported.

Ahmednagar.—In the collectorate, plague occurred in all the tálukas except Karjat; the highest mortality, 1,173, occurred in September. Amongst the Registration Circles the highest number of deaths, 1,576, was recorded in the town of Ahmednagar. In the whole collectorate 93 towns and villages were affected, and there were 3,920 attacks and 2,681 deaths reported, the majority of which occurred in the Chief City and in the neighbouring villages in the Nagar Táluka.

Poona.—In the Poona Collectorate, plague occurred in all the tálukas. The maximum mortality, 5,947, took place in August. The greatest number of deaths from plague, 10,229, was recorded in the town of Poona. The Haveli Táluka, in which the city of Poona is situated, returned 5,037 more deaths from the disease. In the city, cases occurred in every month of the year. In the whole collectorate, 262 towns and villages were affected, and there were 25,239 attacks and 19,047 deaths reported.

Sholápur.—In the collectorate, plague prevailed in all the tálukas except the tálukas of Sángola and Málsiras. 818 deaths were recorded in the town of Sholápur during the latter five months of the year. It was present in the Sholápur Táluka during every month of the year except July, and 771 deaths occurred during the year. Pandharpur Town reported one imported death, but no local case. The total for the year was 59 towns and villages, 2,506 attacks and 1,767 deaths reported.

Sátára.—The collectorate was affected throughout the year and in all Registration Circles except Malcolmpeth. The highest mortality, 2,358, took place in October. Amongst the circles, Karád Rural Circle returned 2,405 deaths. The town of Karád recorded 908 deaths. In the whole collectorate 298 towns and villages were affected, and there were 12,175 attacks and 8,740 deaths.

Ratnágiri.—Was affected during the whole year, and in all the tálukas except Khed. The highest mortality, 132, was in December. There were 60 towns and villages were affected, and 907 attacks and 642 deaths occurred.

Belgaum.—As in 1898, the disease was prevalent during the entire year. In 1899 it had reached its minimum in April, but from that month it showed an increase, till in August the maximum was reached, and for the next two months the mortality was nearly the same, after which a decline set in. The total for the year was 335 towns and villages, 17,875 attacks and 12,772 deaths.

Dhárwár.—Was affected during the whole year. The year opened with 1,869 deaths in January, and the disease gradually declined till April, when the minimum, 96 deaths, were recorded; it again increased rapidly when the maximum, 1,917 deaths were reached in October, 382 towns and villages were affected, and there were 12,066 attacks and 9,183 deaths reported.

Bijápur.—The collectorate was affected throughout the year. The disease which had commenced in September 1898, was on the increase in Deecmber, but in January 1899 there was a sudden fall, which continued until May, when there were only five deaths. The mortality then rose to 12 in June. In July it assumed a greater intensity, and in October it reached the maximum, 752, and fell in November to 535, and in December to 250. In all there were 124 towns and villages affected, and 3,935 attacks and 3,074 deaths.

Kánara.—In July the epidemic reach its maximum. There were 22 towns and villages affected, and there were 565 attacks and 431 deaths.

Surat.—In this collectorate the plague was present in every month of the year, and in all the tálukas except Mándvi, Bárdoli and Chikhli. Bárdoli and Chikhli returned only one and three deaths respectively; the highest mortality, 311, occurred in October. Amongst the Registration Circles the highest number of deaths, 625, was recorded in the town of Surat. In all there were 62 towns and villages affected, and 2,217 attacks and 1,606 deaths.

Broach.—In the collectorate the largest number of deaths was recorded in the first quarter of the year, and then the epidemic declined. In the last two months of the year the district was free. Broach Town Circle suffered most heavily. Twelve villages and towns were affected, and there were 941 attacks and 902 deaths reported.

Kaira.—Plague prevailed chiefly in the first quarter of the year, and then, with a slight recrudescence in August and September, decreased, till in December no cases were reported. Sixty-four towns and villages were affected, and there were 1,645 attacks and 1,516 deaths reported.

Panch Mahál.—The chief mortality occurred in the first two months of the year, the epidemic declining till it ceased in July. Amongst the Registration Circles the highest number of deaths, 456, was recorded in the town of Godhra. In all there were 34 towns and villages affected, and 805 attacks and 700 deaths reported.

Ahmedabad.—In this collectorate, Dhandhuka Registration Circle returned 39 deaths, while 12 deaths were reported from Ahmedabad Town Circle.

Karáchi.—The plague was at its highest intensity in March, April and May, after which it was kept within narrow limits. Karáchi Town Circle suffered the most during the year. In the whole collectorate 20 towns and villages were affected, and there were 3,235 attacks and 2,359 deaths reported.

Hyderabad.—The district was not badly affected till the latter half of the year, but in December a decline set in. Altogether 19 villages were affected, and 1,075 attacks and 922 deaths reported.

Shikárpur.—In this district three imported cases and three deaths were imported during the year.

Jacobabad—In this collectorate the only case and death reported was an imported one.

In the whole Presidency there were 126,287 attacks, and 96,596 deaths from plague, and 2,256 towns and villages were affected, as compared with 110,360 attacks and 86,191 deaths and 1,188 affected towns and villages in 1898. The parts most affected were the collectorates of Poona, City of Bombay, and Belgaum, and the rates of plague deaths per 1,000 in them were 17·9, 19·6 and 12·6 respectively. Násik came next with a rate of 10·03, and then Dhárwár, Sátára, Thána, Karáchi, Bijápur and Ahmednagar, with rates which ranged from 8.7, 7·1, 5·3, 4·2, 3·8 and 3·02 per 1,000; Broach, Surat, Sholápur, Panch Mahals had rates 2·6, 2·4, 2·3, 2·2, respectively; the rates of the remaining affected collectorates were much lower. The rate per 1,000 for the various Registration Districts were as follows:—Western 6·68, Central 6·53, Southern 7·70, Gujarát 1·54 and Sind 1·15.

In January there were 6,933 deaths, and during February and March it rose to 8,961. In April the deaths fell, and continued to fall until the minimum (1,826) was reached in June, they rose again in July and August, and a more distict rise took place in September,

when the maximum (16,974) was recorded, after which a fall took place in October, and continued falling until December.

Dysentery and Diarrhœa.—Dysentery and diarrhœa caused the deaths of 40,348 males and 34,388 females, or a total of 74,736 persons, against 56,789 in 1898 and a decennial mean of 43,918—an increase of 17,947 against the last year and of 30,818 over the decennial mean.

The deaths ascribed to these diseases during the nine years preceding 1897 showed only very slight variations, but in and since 1897 the deaths showed a considerable increase and amounted to nearly double that of any of the nine years already mentioned. The increase has been continued during the present year, though smaller than the year 1897, yet the total is still considerably over any of the nine years previous to 1897. The rate (3·97) was higher than in the year 1898 (3·02). The increase, as in the last two years, is chiefly in the Western and Central Registration Districts, and is most noticeable in the parts affected by famine. The collectorate of Sholápur heads the list with a high ratio of 9·60, Khándesh follows with a ratio of 9·43, Poona with 7·59, Násik with 7·44, and Sátára with 5·95 and the City of Bombay with 5·28. In the Southern Registration District in the Bijápur Collectorate the ratio during the year is higher than the last year and the ten years' mean. In the Gujarát District also there is an increase in every collectorate in the number of deaths ascribed to "dysentery and diarrhœa," but the figures are not high, considering that the district is famine-stricken.

Injuries.—During 1899, 4,108 males and 2,994 females, or a total of 7,102 persons, met with violent deaths. The mortality from these causes is more by 118 than that reported in 1898. Of the 7,102 deaths, 2,772 occurred from drowning, 1,444 resulted from snake-bite, 828 from wounding, 157 from hanging, 109 from poisoning, 90 from attacks by wild beasts, and 1,702 from other causes.

Other Causes.—The recorded deaths from causes other than those specified number 254,872, of which 130,684 occurred among males and 124,179 among females. The total for 1898 was 176,335, so there is an increase of 78,537. Under this heading all deaths are included which cannot be classed under cholera, small-pox, fever, plague, dysentery and diarrhœa or injuries. They have been increasing gradually for the last eleven years, and are now more than treble what they were 11 years before. The increase became more pronounced in 1897 and has continued up to the present year, and will probably be even more next year.

Sanitary Works.

All available information under these sections has been thrown in a tabular form, and will be found in Appendices IV and V.*

There were 166 Municipalities in the Mofussil, with a population of 2,200,455 souls, and an income of £368,446. Out of this income, £182,924, or 49·65 per cent., were allotted for sanitary works, and out of this allotment, £155,778, or 85·16 per cent., were spent. Out of the total expenditure, £67,000, or 43·01 per cent., were spent on conservancy; £31,103, or 19·97 per cent., were spent on improvement of water-supply; £9,398, or 6·03 per cent., on improvement of town sites; £4,172, or 2·68 per cent., were spent on construction and repairs of markets and slaughter-houses; £2,438, or 1·56 per cent., were spent on sanitary arrangements during fairs and festivals, and £41,669, or 26·75 per cent., were spent on sanitary objects, including construction and repairs of tanks, &c.

The Bombay Village Sanitation Act of 1889 has been introduced in five other villages during the year 1899, and abolished in four villages, making a total of 300 since the introduction of the Act in the year 1895, against 299 in the previous year. The committees at Vejalpur in Kálol Taluka of the Panch Maháls District, at Bhadiad and Detraj in the Dhandhuka and Viramgám Tálukas, respectively, of the Ahmedabad District, and at Bulri in the Guni Táluka of the Hyderabad District—in all in four villages—have been abolished, and in five villages, viz., Kálol in Kálol Táluka of the Panch Maháls District, Khatian in Hyderabad Táluka, Old Hála and Bhitshah in Hála Táluka and Beravi in Shahdádpur Táluka of the Hyderabad District, the Act has been introduced and committees established during the year 1899. As the attention of the district

* Not reprinted.

officers has been engaged on famine, no progress has been made in the establishment of village committees under the Village Sanitation Act.

The total number of selected villages in which the Village Sanitary Inspection Book has been introduced during the year is 3,225 against 3,199. Out of this number, five books in the Poona and Sholápur Districts in the Central Registration District, and 12 books in the Hyderabad and Thar and Párkar Districts of the Sind Registration District, have been written up by the Deputy Sanitary Commissioners of those districts, and 342 books in 18 districts have been written up by the Inspectors of Sanitation and Vaccination. Owing to the absence on leave and deputation of the Deputy Sanitary Commissioners on either cholera or famine duty, a greater number of books have not been written up.

Personal Proceedings and General Remarks.

I was in charge of the Department up to 13th January, 1899, when I proceeded on furlough, handing over charge to Lieutenant-Colonel A. W. F. Street, D.S.O., I.M.S., the Senior Deputy Sanitary Commissioner present. This officer in his tour of inspection visited the following places :—Surat, Ahmedabad, Talegaon, Kurla, Kurvandi, Lánowli, Karli, Pandharpur, Poonah, Thána, Dhanora, Modha and Khadakvásla, and when famine relief works were about to be opened in Gujarát, he again visited Ahmedabad, Godhra, Broach, Mehmadabad and Punej, during the month of October, and returned to Poona on 3rd November to hand over charge to Lieutenant-Colonel O. H. Channer, M.B., D.P.H., I.M.S., who took charge on 5th November, and continued to act until the end of the year. During the whole of December Dr. Channer was engaged in the Gujarát Districts, *viz.*, Ahmedabad, Kaira and Broach, in making all the necessary medical arrangements for the new famine relief works that were being opened.

I append a report on the famine work done up to 31st December, 1899.

Report on the Medical Administration of Relief Works during the portion of the year under Report when the Bombay Presidency was affected by Famine.

On the 31st of July of the year under report the monsoon current was reported by the Meteorological Reporter for Western India to be very weak in the Bay of Bengal, and to be becoming weaker day by day in the Arabian Sea, instead of showing any signs of improvement there. There was no monsoon on the Malabár Coast, and only a slight gradient on the West Coast. The skies were becoming more or less clear, and the winds variable in direction. Under such circumstances the prospects of rain were poor, and great anxiety arose throughout the Presidency, especially in Khándesh, Gujarát and Sholápur. On the 31st of August there was no monsoon on the Malabár Coast, while between Bombay and Kárwár the gradient was only about half of the normal. From the following tabular statement comparing the rainfall between the 1st of June and that date at Sholápur, Khándesh, Broach, Ahmedabad and Káthiáwár with the average rainfall for that period and the total average annual rainfall it will be seen that the rains had completely failed in those districts. All crops, especially food-grains, were suffering from the continued drought, and some had been irretrievably ruined :—

Provinces or Districts.	Stations.	Rainfall.		
		From 1st June, 1899, to 31st August, 1899.	Average.	
			From 1st June to 31st August.	Annual.
		In. cents.	In. cents.	In. cents.
Khándesh	Dhulia	6 28	14 12	22 47
	Jalgaon	6 75	24 44	33 42
Broach	Broach	9 25	30 11	38 51
Ahmedabad and Káthiáwár	Viramgám	3 93	25 15	30 95
	Wadhwán	3 06	13 45	18 14
	Dholera	8 74	22 48	30 46
	Bhávnagar	6 02	17 10	22 58
Sholápur	Bársi	6 19	17 14	35 90
	Sholápur	3 09	14 92	29 62

Widespread scarcity being, therefore, threatened, and Government having issued certain Resolutions in July and early in September in connection with it, Lieutenant-Colonel Street, I.M.S., Acting Sanitary Commissioner, lost no time in placing himself in personal communication with the Commissioners of the several divisions while they were all in Poona, and especially with the Commissioner of the Northern Division, in order to be prepared to carry out such famine duties as pertained to his office as soon as occasion should arise.

From reports of the Commissioners it became evident in about the first week of September that in many parts of the Presidency the condition of agricultural labourers had become precarious. Test works were accordingly opened in the Kaira, Ahmedabad and Panch Maháls Districts at once. On or about the 10th of September four test works were started in the Belgaum District, the Collector of Dhárwár was reported to have taken steps to open test works in his district, and about this time the Commissioner of the Southern Division reported that large numbers of people were leaving the Ratnágiri District for Bombay. The Commissioner of the Central Division reported that he was arranging for the drawing up of a programme to determine, if the late rains should fail, when and where large central works should be opened, proposing, meanwhile, to treat as test works small projects entered in the current year's Provincial Budget in any case where Local Fund works were not available for the purpose. Very soon after test works were started in the Ahmednagar and Sholápur Districts.

It was before long manifest, from the numbers of people willing to accept famine wages on the test works, that famine works would have to be started on a large scale. On receipt of a report that this was about to be done in Ahmedabad, Lieutenant-Colonel Street immediately went to Gujarát and took all the necessary steps to make the medical and sanitary arrangements for the camps, following the lines detailed in Section X. of the Thirty-fourth Annual Report of the Sanitary Commissioner for the Government of Bombay, 1897. He then placed these camps in charge of the Deputy Sanitary Commissioner, Gujarát Registration District.

By Government Resolution No. 6534 (Famine), dated the 18th September, 1899, the recommendations in paragraphs 429–460 of the report of the Famine Commission of 1898 were provisionally adopted, with the modifications—

(1.) That the wage of Class I. should be 19 chataks;

(2.) That the wage of Class III.—working children—should be 12 chataks, and that they should be subject to fine; and

(3.) That the minimum wage for adults in Class IV. should be 13 chataks.

Other amendments to the Bombay Famine Code had reference to the point on which statistical information should be recorded, a revision of existing forms being directed in accordance with the recommendations of the Commission, due regard being had to the proposals of the Special Committee appointed to report thereon.

On the 16th of September Lieutenant-Colonel Street applied to Government to revive certain Government Resolutions published in 1896 and 1897, relating to expenditure in connection with, and arrangements for, the management of hospitals attached to large relief works, and to the appointment of District Medical Officers and their establishments, &c.

Government, however, ruled that all applications for funds required by the Sanitary Commissioner for the purposes indicated should be submitted to Government through the Public Works Department, and that he should apply for the requisite sanction regarding the appointment of District Medical Officers when necessary, following in his proposals the precedents created in 1896–97.

New works were opened during the first half of October at Kaira, Khándesh, Thána, and Thar and Párkar, in Sind.

Lieutenant-Colonel Street continued, as new works were opened in Gujarát, to make all the necessary medical and sanitary arrangements, he systematically visiting in the Ahmedabad and Kaira Districts, and the Deputy Sanitary Commissioner, Gujarát Registration District, in the Panch Maháls and Broach Districts.

On the 16th of October he reported to Government that in his opinion the time had come for the appointment of District Medical Officers, under Section 24 (*b*) and Section 48 (*a*) Famine Code, in the Ahmedabad, Kaira, Panch Maháls and Broach Districts. His representation led to the issue of Government Resolution No. 7690 (Famine), dated 28th October, 1899, sanctioning the appointment of three District Medical Officers —one for Ahmedabad, one for West Kaira and Broach, and one for East Kaira and Panch Maháls, the railway being the dividing line between East and West Kaira.

The first two District Medical Officers, viz., Captain W. G. Richards, I.M.S., for Admedabad, and Captain G. O. F. Sealy, I.M.S., for Kaira and Panch Maháls, were appointed on the 30th of October.

By Government Resolution No. 7797 (Fam.), dated 2nd November, 1899, the Collector of Ahmedabad was requested to furnish to Government, through the Commissioner of the Northern Division and the Sanitary Commissioner, a detailed report of the doubtful cases of deaths from starvation mentioned in the remarks accompanying Statement E, for his district, and the Sanitary Commissioner was requested to show, in future mortality returns, the estimated plague mortality in districts where plague was severe, and deducting it from the total mortality, the net estimated mortality due to other causes than plague.

On the 4th November Lieutenant-Colonel Street reported to Government that he had visited the relief works in the Ahmedabad and Kaira Districts and in the táluka of Jalgaon in Khándesh, and that the condition of the people was generally satisfactory and their health fair, as was also the state of things in the Panch Maháls, the camps of which district had been visited by the Deputy Sanitary Commissioner, Gujarát Registration District, who, moreover, reported that he did not observe any signs of distress among the people in several villages which he had inspected. Lieutenant-Colonel Street referring to four cases (with two deaths) of suspicious fever in the Chandola Relief Camp gave it as his opinion that they were not cases of famine fever.

Lieutenant-Colonel Street, D.S.O., I.M.S., was relieved by Lieutenant-Colonel O. H. Channer, D.P.H., I.M.S., who took over charge of the duties of Sanitary Commissioner on the 6th November, 1899.

By Government Resolution No. 8062 (Fam.), dated the 13th November, 1899, the opinions of the Commissioner in Sind, the Commissioners of Divisions, and the Sanitary Commissioner were called for on the points mentioned in a circular letter from the Government of India, having reference as to whether any definition of *starvation deaths*, or any distinction between *starvation* and *privation* deaths could be suggested which could be prescribed for practical adoption, and to meet the request made in 1892 by Her Majesty's Secretary of State for India that all deaths from *starvation* should be entered in returns, difficulty having been experienced in the last famine in distinguishing between actual deaths from *starvation* and deaths from disease accelerated by *privation*.

During November more test and relief works were opened in the Nagar, Sholápur, Khándesh, Poona, and Belgaum Districts, and proposals were made to start works in the Bijápur District.

By Government Resolution No. 8703 (Fam.), dated the 5th December, 1899, the Sanitary Commissioner was requested to submit regularly to Government weekly reports regarding the condition of people on relief works and of inhabitants of affected villages. Also to direct that District Medical Officers should make rapid tours through their respective districts, submitting fortnightly reports on the condition of people visited by them in villages and camps, and that they should endeavour to visit, in the course of their tours, some of the remoter villages, as well as those in proximity to the general lines of communication.

Captain F. D. Browne, I.M.S., was appointed as District Medical Officer for the district of Ahmednagar on the 16th of December.

Up to the end of the year, thirty-six Assistant Surgeons and Hospital Assistants were employed on famine duty. More could have been advantageously employed had any been available. Besides these, a number of dispensary medical officers attended famine camps in addition to their own duties.

Owing to the small number of District Medical Officers, and the heavy organizing work thrown upon the Deputy Sanitary Commissioners of the different districts, it was not possible, before the end of the year, to conduct observations sufficiently exhaustive to warrant the deduction of any conclusions as to the value of the measures adopted. In many parts, moreover, famine had only just commenced before the end of the year. Observations, however, conducted since that date, and experience gained will doubtless afford many indications for the adoption of measures which will enhance the value of that most important branch of famine administration, its Medical Department.

Plague, as in the last famine, was practically non-existent in the open well ventilated camps, and among people leading an out-of-doors life. There were no admissions from cholera during the year into any of the famine relief camp hospitals, and only 21 cases of small-pox, 19 of which were in the hospitals in the Khándesh Collectorate, one in the Ahmednagar, and one in the Kaira Collectorate.

A brief review of each affected district is given below up to the end of the year from the 1st of September.

Khándesh.—Test works were opened in this district in September and freely resorted to. Early in October some of the test works were converted into regular famine relief works. These were visited by Lieutenant-Colonel Street, who organized all the medical and sanitary measures. The price of jowári and bájri in October averaged from 14 to 18 lbs. per rupee, against 52 and 44 lbs. for these grains respectively in October, 1895. There were 303 admissions into famine relief camp hospitals, and 30 deaths. Among those admitted there were 19 cases of small-pox, but none of cholera or plague. Besides the in-patients, 1,303 out-patients were treated. At the close of the year there were 19 relief works. The average daily number of *workers* during the week ending the 30th of December was 164,090 ; of *dependants* 11,114 ; and of those in receipt of gratuitous relief 198 (in four villages).

Ahmedabád.—Test works were opened early in September and rapidly extended, many being soon converted into regular famine relief works. Lieutenant-Colonel Street, and after him Lieutenant-Colonel Channer, I.M.S. (who succeeded him as Acting Sanitary Commissioner in November), spent much time in organizing the necessary medical and sanitary arrangements, and in travelling about and supervising the work of the Medical Officers. No sowing operations could be carried out, except where well irrigation was possible. The condition of the cattle was very bad, large numbers being sent to grazing grounds, and over 2,000 being in cattle relief camps in December. Between July and December the price of jowári ranged from 17 to $18\frac{7}{8}$ lbs. for the rupee, and that of bájri from $15\frac{2}{5}\frac{9}{0}$ to $16\frac{3}{4}$ lbs. As many as 2,220 were admitted into hospitals, of whom 562 died. There was no cholera, plague or small-pox, but dysentery accounted for 578 admissions, diarrhœa for 383, and fever for 678. Besides the in-patients, 4,508 out-patients were treated. At the close of the year there were 12 relief works and two test works. The average daily number of *workers* during the week ending the 30th of December was 37,383 ; of *dependants* 8,980 ; and of those in receipt of gratuitous relief 4,150 (in 308 villages), and 3,670 (in poor-houses).

Kaira.—Works were opened in this district also early in September. Water in the tanks was rapidly drying up, and the supply of fodder was being rapidly exhausted, and large numbers of cattle were dying. During the week ending the 9th of September the average daily numbers on works had risen to 3,649. Between July and December the price of jowári ranged from $16\frac{1}{4}$ to $18\frac{1}{3}$ lbs. per rupee, and that of bájri from $14\frac{1}{2}$ to $16\frac{5}{1}\frac{}{4}$ lbs. There were 836 admissions into hospital and 128 deaths. There was no cholera or plague, but one case of small-pox. Ninety-three admissions were due to dysentery, 189 to diarrhœa, 149 to fevers, and 267 to emaciation. Besides the in-patients, 1,065 out-patients were treated. A District Medical Officer was appointed on the 30th of October. At the close of the year there were seven relief works. The average daily number of *workers* during the week ending the 30th of December was 11,807 ; of *dependants* 1,865 ; and of those in receipt of gratuitous relief 1,053 (in 242 villages), and 858 (in poor-houses).

*Panch Mahál*s.—Works were started early in September and on the 2nd there were over 800 being relieved. The want of rain was felt at a very early date, and fodder became very scarce. This affected the cattle seriously and many died. Sowing operations were attempted where well irrigation was possible, but towards the end of November hope was given up of obtaining any rabi crop. During the famine months the price of maize ranged from 16 to $18\frac{2}{3}$ lbs. per rupee, and that of bájri from 14 to $16\frac{1}{2}$ lbs. There were 60 admissions into relief camp hospitals and five deaths. None of these admissions were due to cholera, plague or small-pox. Besides the in-patients, 165 out-patients were treated. The medical arrangements were at first in the charge of the Deputy Sanitary Commissioner, Gujarát Registration District, but a District Medical Officer was appointed on the 30th of October. At the close of the year there were five relief works. The average daily number of *workers* during the week ending the 30th of December was 13,361 ; of *dependants* 2,209 ; and of those in receipt of gratuitous relief 95 (in 14 villages).

Broach.—Test works were opened in September, and, being freely attended, soon developed into regular famine relief works, and for the week ending the 30th September the average daily number being relieved exceeded 2,000. During October the supply of grain was insufficient, fodder was being largely grown by well irrigation, and wells were being dug freely. About the middle of that month the standing cotton crop was

estimated to be 10 annas in Anklesvar, 8 annas in Broach, and insignificant elsewhere. At Jambusar it was being used for fodder. The jowári crop was estimated to be 4 annas in Anklesvar, and elsewhere practically *nil*. In November large numbers of cattle were sent to graze in the Thána forest land. The numbers on relief works continued to increase, and in December poor-houses were opened, first at Vágra, Broach and Anklesvar, and soon after in all the tálukas. The average daily number on relief during the week ending the 16th December exceed 4,000. Between July and December the price of jowári remained fairly stationary at between 17 and 18 lbs. per rupee, and of bájri between $15\frac{1}{6}$ and $16\frac{2}{3}$ lbs. There were 87 admissions into relief camp hospitals and 12 deaths. Thirty-five of the admissions were cases of child-birth. Besides the in-patients there were 1,959 out-patients treated. No epidemic disease. At the close of the year there were 14 relief works. The average daily number of *workers* during the week ending the 30th of December was 64,070 ; of *dependants* 9,089 ; and of those in receipt of gratuitous relief 3,953 (in 401 villages), and 390 (in poor-houses).

Surat.—About the first week of October rain was beginning to be urgently needed to save some of the crops. There was, however, no hope of saving any of the fodder crops, and the price of grass was so high that many of the cattle were sent to graze in the Dang country. The labouring classes finding but little to do in the fields were maintaining themselves chiefly by selling fuel and grass-cutting. A test work was opened at Dehan towards the end of October, and during the week ending 2nd December a daily average of 7,990 people were on relief. More test works followed soon after in Olpád and Mándvi, and were freely resorted to. No admissions into any hospital were reported before the end of the year among those on relief. The price of food-grains rose in October slightly, and remained more or less stationary till the end of the year, up to which time also the condition of the people, excepting those in the Olpád and Mándvi tálukas, was fair. At the close of the year there were two relief works. The average daily number of *workers* during the week ending the 30th of December was 5,299 ; there were no *dependants* and none in receipt of gratuitous relief.

Thána.—In December the condition of cultivators and cattle was satisfactory, and there was, for the time, sufficient employment for agricultural labourers and wild tribes. People from above the Ghauts were, however, coming into Sháháda, Mokháda and Kalyán in search of work. Beggars also and other immigrants from Gujarát and Káthiáwár were flocking into Kalyán, Bhiwndi and other parts. The numbers on Local Fund works at Dáhánu and Umbargaon were increasing, and it was proposed to convert these into famine test works in the following month.

Ahmednagar.—Test works were started in September in this district and freely resorted to, there being about 1,900 average daily workers during the week ending the 7th October. Two hundred people from Native States had come on to the test work in Nevása, and later on 500 more came. About the middle of October, the condition of agricultural labourers was reported to be deteriorating, and that of weavers to be getting bad. During the last week in October about 7,000 persons were on test works, and the condition of labourers and weavers was getting worse. Early in November more test works were opened, and later on in the month some test works were converted into regular famine relief works. About the middle of December there were six relief works and eight test works, and during the week ending 16th December an average daily number of over 18,000 on relief. A District Medical Officer was appointed on the 16th of December. The price of jowári in November and December ranged from $16\frac{3}{8}$ to $17\frac{1}{7}$ lbs. per rupee, and of bájri $16\frac{2}{3}$ to $16\frac{1}{3}$ lbs. Only 16 admissions and one death were reported in Famine Relief Camp Hospitals during the year. One of these was a case of small-pox, but none were due to cholera or plague. Besides the in-patients, 159 out-patients were treated. At the close of the year there were 10 relief works and four test works. The average daily number of *workers* during the week ending the 30th December was 53,505 ; of *dependants* 7,945 ; and of those in receipt of gratuitous relief 1,371 (in 549 villages).

Sholápur.—Early in October, the price of food-grains rose generally throughout the district on account of extensive exports of grain to Gujarát and Káthiáwár. This caused much distress among the poorer classes, and crowds of beggars flocked into Sholápur City some of whom (chiefly lepers and the blind and infirm) were admitted to gratuitous relief to prevent actual starvation. About the middle of October the local demand for labour was insufficient to meet requirements, and 958 persons in Sholápur City were getting gratuitous relief, 959 in Sángola táluka, and 49 in Málsiras táluka. A test work had been opened on the 10th, and workers joined on the 14th. Other test works were opened

in Sángola and Bársi tálukas soon after and were freely resorted to. More test works were started in November, and during the week ending the 2nd December nearly 15,000 people were being relieved. Towards the end of December there was a daily average of nearly 60,000, and many of the test works were converted into regular famine relief works. During the famine months, the price of jowári ranged between 17½ and 22⅜ lbs. per rupee, while bájri remained stationary at about 18⅘ lbs. Only two admissions into Relief Camp Hospitals were reported during the year, late in December. At the close of the year there were 14 relief works. The daily average number of *workers* during the week ending 30th of December was 64,678; of *dependants* 22,552; and of those in receipt of gratuitous relief 5,070 (in 376 villages).

Násik.—Early in October the want of rain commenced to be felt and crops were withering. Cattle in the plains commenced to suffer from scarcity of water and fodder. The condition of cultivators was middling, of labourers bad, and of artizans fair. Two test works had been started and two more followed, and during the week ending the 4th November over 2,000 people were on relief. During November another test work was opened and freely resorted to. In December many of the test works were converted into relief works, and the numbers of workers rose. In November and December the price of jowári ranged from 16⅗ to 18⅜ lbs. per rupee, and of bájri from 16½ to 17 lbs. No admissions into hospitals were reported among those on relief during the year. At the close of the year there were two relief and five test works. The average daily number of *workers* during the week ending the 30th of December was 19,401; of *dependants* 2,883; and of those in receipt of gratuitous relief 218 (in 93 villages).

Poona.—In September jowári was 23½ per rupee and bájri 21 3/10 lbs. Jowári remained stationary in October, but bájri became dearer, and early in that month distress commenced among low caste people and low paid village servants. Labourers and agriculturists soon commenced to feel distressed also, on account of high prices and the coming to a standstill of agricultural operations in consequence of want of rain. So far no noticeable change was observed among hill tribes who were engaged in the collection of hirdas. Test works were started, and during the last week of October over 1,000 workers had resorted to them. In November more test works were successfully started, and towards the end of that month one relief work as well. There was no marked deterioration in the condition of the people, but lack of employment drove them to the works. The condition of weavers, artizans, and hill-tribes remained satisfactory throughout December. No admissions into hospitals were reported before the end of the year among workers. The daily average number of persons on works during the week ending the 30th of December was 12,185, and of those in receipt of gratuitous relief 1,302 (in 518 villages).

Sátára.—In September two tests works were started in this district, the prices of food having risen in several tálukas, and distress being felt by the poorer classes, especially at Khánápur, Khatáv and Khándála. Soon after five other test works were started, and the daily average number on relief was, during the week ending the 21st October, nearly 2,000. The numbers gradually rose, but up to the end of the year no regular famine relief works were started. During the week ending the 30th of December there were four test works, the average daily number on these works was 12,482, and there were 206 *dependants*.

Bijápur.—Early in October the poorer classes suffered from the rise in prices of food-grains in consequence of extensive export of grain into Gujarát, and one test work was opened. The numbers of workers slowly rose, and more test works were open, but up to the end of the year it was not found necessary to open any regular famine relief works. During the week ending the 30th of December there were three test works and an average daily number of 3,861 *workers*.

Belgáum.—At the close of the year there were three test works in this district, with an average daily number, during the week ending the 30th of December, of 1,694 *workers*.

Dhárwár—At the close of the year there were two test works in this district, with average daily number, during the week ending the 30th of December, of 199 *workers*.

Report of the Sanitary Board for the Year 1899.

Preliminary.—Plague and famine have again pressed heavily on Municipalities, and we can only draw attention to paragraph 1 of our report of last year.

Hyderabad.—The municipality, owing to dissensions amongst themselves, have been very dilatory in constructing the engine house at the river lift at Giddu, and in erecting the new engines. The necessity for having the latter working before the hot weather has been strongly urged on the President.

The plans and estimates, prepared by the Sanitary Board, for the final completion of the water works, are still under consideration by Government.

Ahmedabad.—The drainage scheme, prepared by Mr. Baldwin Latham, is still under discussion; but little progress is likely to be made until a special engineer is put in charge, as the local Executive Engineer's time is so fully occupied.

Kaira.—At the request of the Collector, the Sanitary Engineer went more fully into the matter referred to in paragraph 6 of last year's report. The details necessary for getting up the project are ready, and will be worked up as soon as the Poona Drainage Scheme is disposed of.

Mehmadabad.—A similar remark applies to this place, *vide* paragraph 7 of last year's report.

Yeola.—Practically no progress was made with the water works for this town. Up to March, 1899, the expenditure was £3,746, out of the estimated cost of £8,528. It is still under consideration whether the machinery and pipes should be obtained through the Secretary of State, or purchased locally. The work is under the Public Works Department, but the Executive Engineer states that he cannot spare any time for this work.

Ahmednagar.—The completion of the Kapurwadi tank is now being carried out as a famine relief work. It is hoped that it will be finished before the monsoon, as the wells seem to be all drying up, and the sub-soil water apparently is disappearing altogether from above the rock-level. The distribution scheme for the remaining two-thirds of the town, in connection with this tank, will shortly be forwarded to Government; but unless they grant a loan it will be impossible to carry it out.

Poona.—The drainage scheme prepared by the Sanitary Engineer was generally approved of by Government, and by the municipality; and also by Mr. Santo Crimp, whose presence in Bombay was taken advantage of by the municipality. On his advice, an effluent farm was finally adopted by the municipality; and the original scheme is now being altered, by doing away with the Septic tanks at the out-fall, which were necessary if the effluent was to be turned into the river instead of on to a farm. The out-fall can now be lowered some 15 feet, thus extending the gravitation area, and reducing the Shone system area. The sewers will discharge into a balancing tank, capable of holding 7½ per cent. of the day's maximum flow; and it will be pumped thence, by Worthington Triple Expansion Engines, through a 25-inch steel main, for a distance of 6½ miles; and with a lift, including friction, of 190 feet to the out-fall. There it will be passed through macerating tanks, as at Wimbledon; and the effluent will be used for crops. The experiments made with fodder crops irrigated with the effluent showed startlingly successful results, in comparison with heavy dressings (20 tons per acre) of poudrette, and of farm yard manure. The comparative crops of sugarcane on the effluent, and on these manures, will be cut, and the juice tested, about the end of April; and if this is as successful as the fodder crops, the scheme will practically cost the municipality nothing, provided the farm is worked intelligently by a trained European, as suggested.

A water-supply scheme for the city is also under preparation by the Sanitary Engineer, in order to provide a sufficient head for the water-closets in the higher portions of the city, and a better supply and distribution all over the city. Both projects will probably be ready for final discussion in June; but here again, without Government assistance in the shape of a loan, and a favourable rate for the canal water, nothing can be done.

Akalkot.—The oil engines, which were almost a new departure in this country, have been working so satisfactorily that their extended use for small projects will probably be adopted.

Regarding the other towns and projects referred to in last year's report, no progress has been made, and each year only enforces the urgency of the matter referred to in paragraph 19 of last year's report; especially in a year like this, when every executive engineer is over-worked, owing to famine relief.

Miscellaneous.—The Board advised on the proposals for water-supply to the Central Jail at Hyderabad, on the Ahmedabad Sewage Farm and on the water-supply to Government House, Mahábaleshvar. The Sanitary Engineer, in conjunction with the Collector, also reported on the military proposals regarding the sanitation of the Kamatipura section of the Sadar Bazár at Poona. The plan and estimate for the drainage scheme of the Sadar Bazár have been sent to the Military authorities, with a view to its being carried out at the same time as the city scheme.

ABSTRACT OF THE REPORT OF THE HEALTH OFFICER OF THE PORT OF BOMBAY FOR THE YEAR ENDING 31ST DECEMBER, 1899.

The following table gives a summary of the shipping and health of the Port of Bombay, and of the work in connection therewith, for the year ending 31st December, 1899 :—

Vessels including Country Craft.	Number of Vessels inspected.	Number of Persons inspected, including Crew on Vessels.	Number of Native Crew and Third Class or Deck Passengers disinfected during the period extending from 14th February to 31st December.	Number of Vessels disinfected.	Number of Persons Vaccinated.	Number of Persons segregated or rejected.	Diseases and Number of Cases of each.						
							Plague.	Cholera.	Small-pox.	Measles.	Scarlatina.	Chicken-pox.	Jigger.
Entered	1,198	76,910	3,485	32	32	238	4	—	1	2	5	7	168
Left	64,594	1,116,429	44,864	—	—	17,424	117	—	—	—	—	—	—
In Harbour during the year ...	30	—	—	30	—	—	34	1	1	5	—	—	—
Total	65,822	1,193,339	48,349	62	32	17,662	155	1	2	7	5	7	168
1898	71,498	1,207,571	—	49	150	19,138	118	5	6	4	3	10	—

The foregoing table shows that 65,822 vessels of all sorts, with 1,193,339 crew and passengers, were examined during the year. The number includes every person who left Bombay by sea during the year, as well as those who arrived from certain infected ports.

It further shows that the clothing and bedding of 44,864 native crew and third-class or deck passengers who sailed on vessels for ports out of India were disinfected during the period extending from 14th February to 31st December, 1899. It also shows that the baggage of 862 returning pilgrims and 2,623 deck passengers who arrived from East African (Jigger infected) ports was disinfected.

The total number of plague cases detected during the year 1899 in connection with the shipping was 155 against 118 for the year 1898.

The following table furnishes further particulars regarding vessels which entered the port during the year 1899 :—

Year.	Total Number of Steamers and square-rigged Vessels which entered Bombay Harbour from Ports other than Indian Ports.	Number of Passengers only.	Total Number of Native Sailing Craft which entered Bombay Harbour from Ports other than Indian Ports.	Number of Passengers only.	Total Number of Steamers and square-rigged Vessels which entered Bombay Harbour from Indian Ports.	Number of Passengers only.	Total Number of Native Sailing Craft which entered Bombay Harbour from Indian Ports.	Number of Passengers only.
1899 ...	527	25,660	250	484	1,375	309,915	44,267	6,001
1898 ...	557	28,484	281	215	1,542	269,725	40,190	1,986

The total number of persons, including crew who arrived by these vessels, cannot be given, as no record is kept of the number of crew on most of the vessels entering the port. Of the 342,060 passengers who are shown in the above table, 10,520 were troops, 862 Mecca pilgrims, and the remaining 330,678 principally passengers from ports in close proximity to Bombay.

The following table gives the number of ships which had infectious disease on board on or before entering the harbour :—

Class of Vessels.	Number of Ships.	Total Number of Crew and Passengers inspected.	Number of Passengers from East Africa disinfected on account of presence of Jigger among them.	Diseases and Number of Cases of each.						Number of Persons Vaccinated.
				Plague.	Small-pox.	Measles.	Scarlatina.	Chicken-pox.	Jigger.	
Troop-ships	1	1,313	—	—	—	—	5	—	—	—
Vessels from Jigger-infected Ports ...	23	4,633	2,623	—	—	—	—	—	168	—
Other Vessels	8	1,678	—	4	1	2	—	7	—	32
Total	32	7,624	3,623	4	1	2	5	7	168	32
1898	20	12,321	—	5	8	3	3	5	—	150

Vessels which became infected while in port are not shown in the above table, but are noticed in the table on page 190.

Five cases of scarlatina which are shown in the foregoing table as having occurred on board a troop-ship were landed and isolated in the Military Cantonment at Colába. One of the P. & O. steamers arrived with a case of small-pox amongst her European passengers. The case was removed to the Saint George's Hospital, and such of the persons amongst the crew and passengers as were found unprotected by previous vaccination or small-pox, and who were willing to submit to it, were vaccinated. The total number of persons thus vaccinated was 32.

One vessel arrived with two cases of measles and three vessels with seven cases of chicken-pox. The cases of measles and chicken-pox were removed to hospitals on shore, and the necessary precautions for the disinfection of the vessels were taken.

Three steamers entered the harbour each with a case of plague on board, and one landed a native passenger suffering from plague at an intermediate port during her voyage from Hongkong to Bombay. The three cases of plague were sent for treatment to the Plague Hospital, and the ships by which they arrived were thoroughly disinfected in accordance with the Venice Convention Regulations.

It will be seen from the foregoing table that 23 vessels with 4,633 crew and passengers arrived at the Port of Bombay from Jigger infected ports on the south-east coast of Africa, 168 persons were found to be suffering from Jigger and ulcers due to Jigger, and were removed to the Goculdas Tajpal Hospital for treatment. In each case where sand ballast was found on a Jigger infected ship it was discharged into the sea and the vessels were thoroughly disinfected with carbolic solution or perchloride of mercury of the prescribed strength. The clothing, and effects of all passengers on ships among whom Jigger cases were detected were thoroughly disinfected in a steam sterilizer before they were allowed to go to their destination. The passengers were made to understand the importance of immediate resort to the nearest Government dispensary in the event of their suffering from painful swellings on their limbs or between their toes or under their toe nails.

In accordance with Government Notification No. 4617—4858-P., dated the 17th August 1898, and Notification No. 3893-P., dated the 14th June 1899, under the Epidemic Diseases Act and the Medical Inspection Rules framed under the Indian Ports Act, the examination of incoming vessels was imposed only on arrivals from plague, jigger, and cholera infected ports during the year. Vessels which had infectious disease dangerous to life at the time of arrival or during the voyage were also medically examined. The ports against which the inward inspection was imposed were Ulwa, Káthiáwár Coast, Karáchi, Persian Gulf Ports, Jeddah, Alexandria, Mauritius, Ports on the South-east Coast of Africa, Hong Kong and other Eastern Ports.

Owing to the outbreak of cholera in an epidemic form at Karáchi during the months of May, June, July and August 1899, all vessels from that port were carefully inspected on arrival with a view to prevent the importation of cholera into the City of Bombay. The vessels were thoroughly disinfected and the decks were scraped and afterwards washed with a five per cent. solution of carbolic acid or a solution of perchloride of mercury of the strength of 1 in 1,000. The bilge water was pumped out and a fresh

supply of drinking water was stored on board. Vessels trading between Bombay and Karáchi were recommended not to take on board at Karáchi any drinking water.

The following table shows the total number of vessels, crew and passengers examined on arrival at Bombay from the above-mentioned ports.

Months.	Number of Vessels inspected.			Number of Persons inspected.							Number of Persons segregated.			Number of Plague cases found on arrival at Bombay.
				Passengers.		Crew.		Total.						
	Number of Steam-ship and Square-Rigged Vessels.	Number of Native Sailing Craft inspected.	Total.	Steam-ship and Square-Rigged Vessels.	Country Craft.	Steam-ships and Square-Rigged Vessels. In accordance with the Medical Inspection Rules prescribed in General Department (Plague) Notification No. 4616—4857-P., dated the 17th August 1898, and Notification No. 3892-P., dated the 14th June 1899, the medical examination of the crew and passengers of all vessels, including Native Sailing Craft which left Bombay for ports out of India was carried out by day *on shore* in sheds specially arranged for that purpose. Persons who embarked for vessels in the stream were examined at Madi Bandar or Ballard Pier while persons who embarked on vessels in the Docks were examined in the sheds alongside the vessel. There were also three centres in the harbour for the examination of the crews of the smaller Native Craft which run to the ports in close proximity to Bombay. As soon as the monsoon was over, another centre of examination was established at Warli and Máhím Bandars on the other or north-western side of the Island.

The result of the outward inspections for the year under report is given in the above table. It shows that out of 1,116,429 outward bound crew and passengers inspected, 17,424 or over 1½ per cent. were prevented from sailing. Many of them were suffering from fever and were turned into the town for a day or so until their temperature fell to normal. The remainder were sent to the Port Observation Camp, where 117 of them developed plague.

Out of the 64,594 outgoing vessels with 550,280 crew and 566,149 passengers examined during the year, 297 vessels left with 28,815 crew and 23,811 passengers for Aden, Red Sea and Europe ; 527 vessels with a total of 27,235 crew and 14,622 passengers for ports out of India other than Aden, Red Sea, and Europe, and the remaining 63,770 vessels with 494,230 crew and 527,716 passengers for Indian Ports including Burmah.

In addition to the medical examination of crew and passengers which was conducted by day on shore prior to their embarkation as directed by the Venice Sanitary Convention, the ship's company was again inspected on board before the issue of a Bill of Health immediately before departure from this port, This means that the crew of almost all vessels bound to ports out of India were examined three times, first when they were shipped, secondly when their kit was being disinfected, and thirdly immediately before the vessel sailed.

The form of Bill of Health issued to vessels sailing for foreign ports was the same as that prescribed by the Government of India in 1890, with certain additions and alterations made in it. The wording of the Bill of Health runs as follows. The additions made to the original form are in italic :—

Bill of Health.

"This is to Certify that the (steamer) ' ' sailing under the flag and under the command of Captain , of , tons bound for with a crew* of persons and passengers, and laden with a cargo of , is at the time of leaving this port in a satisfactory sanitary condition, and that no case of infectious disease dangerous to life exists among its officers, passengers or crew, *who have been examined by day on shore before embarkation and found free from plague.*

It is further certified that the Town and Port of Bombay are at present free from Epidemic Cholera, Yellow Fever, and all other dangerous Epidemic Diseases, *except plague which exists in an epidemic form.*

The clothing and bedding of the native crew and of the third class or deck passengers have been disinfected on shore."

---

* Including Officers and able-bodied seamen.

During the year under report 2,891 steamers and square rigged vessels were examined. All of them were certified to have sailed from Bombay in a satisfactory sanitary condition. The Commanders and Agents have been very careful in paying attention to the sanitary state of their ships and in all cases they have cheerfully carried out the instructions and advice of the Port Health Officer. The forecastles were painted or limewashed before departure. Ships in ballast had their 'tween decks and holds cleaned before leaving the harbour, and in the case of coal ships the 'tween decks of which are used as latrines by the four or five hundred coolies who are employed in discharging the coals, were thoroughly washed down and in most cases limewashed or disinfected with a solution of carbolic acid. 61,703 Native Sailing Craft were inspected during the year. Their bilges were generally clean at the time of inspection. Those that were not clean had to pospone their departure until thoroughly cleaned.

Infectious Disease on Vessels in the Harbour.—The following table includes all steamers, square rigged vessels and Native Craft which became infected while at sea, or whose crew and passengers developed plague after arrival. It also shows the number of dock labourers or coolies who were removed to Plague Hospitals from the Docks and Bandars :—

Months.	STEAMERS.									BUGGALOWS, TONIES, PROWS, STEAM-LAUNCHES, &c.										Number of Persons who were attacked with Plague at Bandars and in the Docks.		TOTAL NUMBER OF CASES OF INFECTIOUS DISEASES IN THE BOMBAY HARBOUR.

All the above vessels including those in the table on page 187 were thoroughly disinfected in accordance with rules laid down in the Venice Sanitary Convention and those framed under the Indian Ports Act.

Port Observation Camp.—During the first two epidemics and up to the 15th January, 1899, some of the rejected persons from vessels were sent to the Plague Committee's Camps for observation and disposal. After the 15th January, 1899, the municipal authorities were unable to admit such people into their observation hospital at the Modikhana owing to want of accommodation. A part of the old Modikhana Camp was therefore taken over by Government from the municipal authorities and converted into an observation camp for harbour purposes. This camp was opened on the 16th January, 1899, with an establishment of one Hospital Assistant and one Ayah. One sweeper was also sanctioned but his services were not utilised, as arrangements were made with the Public Health Department of the Bombay Municipality for sweeping the camp. One of the Senior Medical Officers of the Port Health Staff was detailed from time to time to supervise the general working of the camp. Food was supplied to the destitute and sick people at the cost of Government.

The number of persons who developed plague among those segregated in the camp during the year was 121. Precautions were taken to have all the sheds thoroughly disinfected twice a week with the standard solutions of perchloride of mercury. As soon as a case of plague developed in a shed, the latter was at once disinfected with a solution of perchloride of mercury and was not used for some time after. Persons sent to the observation camp were kept until their temperature fell to normal or until it was certain that the fever from which they were suffering was not due to plague. Shortly after the camp was opened it was found that some persons were taking money from some of those placed under observation or from their friends on the promise that they would obtain immediate release from the camp. One man was detected, convicted and got six months' imprisonment.

Disinfection of Ships and General Health of the Shipping.—During the year 1899 the total number of infected vessels of all sorts, disinfected under the personal supervision of the Health Officer of the Port or of his staff, and assisted by the Water Police, was 62.

The Resident Transport Officer and the Senior Naval Officer arranged for carrying out the Port Health Officer's recommendations for the disinfection of transports on which cases of infectious diseases occurred.

The general health of the harbour population was fairly satisfactory. The various hospitals in the City admitted during the year 790 persons connected with the shipping. This number of admission is exclusive of plague. The Saint George's Hospital admitted 425 Europeans, of whom 13 died; the Jamsetji Jijibhoy 73 natives, of whom 7 died; and the Goculdas Tejpal 292 natives, of whom 18 died.

No deaths occurred from the effects of cleaning the bilges of ships during the year, but the Coroner of Bombay held 20 inquests on persons who died from accidents other than bilge-poisoning on board ships.

Red Sea Pilgrim Traffic.—Owing to the existence of plague in Bombay, the pilgrim traffic between the infected Indian Ports and Jeddah was stopped during the year 1899. Accordingly no vessels with Mecca pilgrims left this Port for Jeddah during the year. During the year 862 pilgrims returned by ship from Jeddah, *via* Aden and other routes. The baggage of all the returning pilgrims was disinfected at the Port Health Disinfecting Station. The pilgrims for up-country were not allowed into the town, but were sent direct from the ship to their homes by rail at the expense of Government.

Emigration Traffic.—The emigration traffic from Bombay was closed in the year 1897 and continued so up to date. Accordingly, no ship with emigrants sailed from this port, with the exception of three vessels ("Sultan," "Chindwara," and "Canara") with 28 emigrants. These emigrants were segregated for 10 days before they were allowed to depart.

Sanitary state of the Harbour and Foreshore.—Owing to pressure of work the usual inspection of the harbour and foreshore was not made during the year, and consequently no remarks are made on their sanitary conditions.

Plague.—Owing to the rigorous nature of the examination of crew and passengers and the disinfection of suspicious clothing and bedding, very few fully developed plague cases were found at the time of inspection. The people did not present themselves, if they considered they were in any way suspiciously ill, so as to avoid the risk of being detained. Special care was taken in recording temperatures, as many of the persons who developed plague had a temperature of under 100° F. at the time of rejection.

With a view to prevent the spread of plague to countries out of India, the Port Health Officer made proposals to the effect that (*a*) Commanders of vessels bound for ports out of India should ship their native crew as many days as possible, say seven days, before the time fixed for leaving the port, and (*b*) that Commanders be requested to take every reasonable precaution that their native crew did not enter the town. This could be done under the Epidemic Diseases Act. The proposals were made with a view to get the native crew for vessels out of, and keep them out of, the infected parts of the city. By doing this, they would in the first place escape many of the risks of contracting plague, and secondly, if they were in the incubation stage when shipped, the disease itself would be fully developed before the vessel left the port. These proposals were forwarded to the Chamber of Commerce for their opinion. The Committee of the Chamber expressed an opinion that the proposal to keep crews on board their ships for some days before sailing was impracticable. The system followed by ships with native crews is that on arrival in port the crew is paid off, and the same crew is customarily signed on again just before sailing. The Committee further submitted that if it be indispensable that lascars should be protected from contagion, Hogg Island or some equally isolated place, ought to be utilized as a depôt from which drafts of seamen could be made to ships. In conclusion they stated that the enquiries instituted tend to show that the existing regulations under the Venice Convention are in themselves all that can be practically desired, and that every effort is made by Agents and Commanders to secure a faithful observance of those regulations. After the careful consideration of the proposals, Government passed an opinion that the thorough and strict medical examination now enforced, coupled with the disinfection of clothing and kit, is showing itself to be a very effectual safeguard, and till examination and disinfection prove ineffectual the principles of the Venice Convention had better be adhered to.

The rigorous and very searching examination enforced on each individual who departed from this port, the thorough disinfection of suspicious clothing, bedding and boxes of those who left for ports out of India and the rejection of all persons who showed any suspicious signs or symptoms show a satisfactory result by the almost complete absence of genuine plague cases on the hundreds of ocean-going steamers which left Bombay during the year under report.

The following ocean-going vessels were reported to have had plague on board after leaving Bombay.

(*a*) On the 18th of January, 1899, the S.S. "Booldana" left the Port of Bombay for Rangoon, and was reported to have conveyed out of this port a case of plague. This was a native crew. At the time of the inspection of the vessel one of the saloon crew, a native cook, was missing. It turned out that the missing cook was at the time suffering from fever on shore, and did not like to face the inspection. He died of plague on shore a few days after the vessel sailed. The man, who developed plague on board after leaving the port, was another native cook who was found to have resided in the same house as that in which the first cook died from plague. This cook who developed plague on board was therefore a "contact."

(*b*) A "suspicious" case of plague was reported to have got away from Bombay in a vessel bound for Aden. This was on the S.S. "Caledonia" (running between Bombay and Aden), which left Bombay on 1st April, 1899, and arrived at Aden on the 6th idem. A man named A. Dias, a Portuguese Scullian, was found suffering from fever and enlarged glands on the 7th, and was landed in accordance with the standing order of the Company. The man was said to be suffering from Pestis Minor by the Aden authorities, and on the day the vessel left Aden, *viz.*, 10th April, 1899, on her return voyage to Bombay, the man's temperature had fallen. The man's name was entered by us in the official Log Book before the vessel left Bombay, certifying that he was suffering from chronic enlarged glands, so that in the event of his suffering from fever in a foreign port the captain may be able to produce it to show that the glands from which he was suffering were not due to plague. The Log Book was not produced when the man was landed from the vessel.

(*c*) The S.S. "Peninsular," which left Bombay for Aden and London on 23rd September, 1899, is said to have landed at Plymouth a lascar who had suffered from plague during the voyage, and was in a state of recovery at the time of his arrival at Plymouth. It has been stated by the Port Medical Officer, Plymouth, that on 21st October, 1899, he made an incision into the bubo and obtained a pipette of blood and serum, which was submitted to Dr. Klein for examination, with a negative result.

(*d*) The Civil Surgeon, Muscat, reported the detection of an imported case of plague on the 13th April, 1899, in the town of Muscat, from Bombay. The man, who is said to have had plague in Muscat 16 days after arrival, arrived in Bombay from East Africa in the S.S. "Sultan" on the 8th March, 1899, and embarked on the S.S. "Pachumba" on the 23rd March for the Persian Gulf *viâ* Karáchi. There is nothing to show that he had fever or a bubo of any kind when he left Bombay, or when he arrived at, or left, Karáchi. According to the Civil Surgeon at Muscat the man is said to have developed a bubo on the 28th March, the day before he arrived at Muscat, and although he was placed in quarantine on arrival, the bubo was not discovered until the 13th April; that is, 16 days after arrival, or 21 days after leaving Bombay. The man was alive, and the diagnosis of plague was not confirmed by a bacteriological examination.

(*e*) The *Pall Mall Gazette* of 25th July, 1899, announced that an outbreak of plague occurred on board the S.S. "Dictator," bound for Liverpool, and laden with grain from Bombay and Karáchi. The S.S. "Dictator" left Bombay in water ballast for Karáchi on the 14th June, 1899. She carried a crew of 14 Europeans and 49 Natives. All the Natives' clothes, bedding and boxes were disinfected before being allowed on board. The vessel carried no passengers. The "Dictator" arrived at Karáchi all well on the 16th June, 1899, and remained there for nine clear days, during which time she took on board a cargo of wheat, and shipped one Native as a fireman. On the "Dictator's" arrival at Perim on the 4th July, 1899, a sick Native was shown to the Port Surgeon, who found him suffering from an enlarged gland in the right groin, and a temperature of 101° F. These were said to be due to the man having fallen off a ladder. The Port Surgeon left the sick man on board, gave the captain certain instructions, and informed the Suez authorities. It was stated by the President of the Quarantine Board in Egypt that when the "Dictator" arrived at Suez on the 9th July, 1899, she had two cases of plague and three suspects on board. A bacteriological examination was made after arrival at Suez, but no plague microbes were found in the man said to be suffering from plague.

The last two cases—"Pachumba" and "Dictator"—should not be counted against Bombay, because, although the vessels left this port they had been to another Indian plague port afterwards, and were passed in by the authorities at that port as free from plague. They are simply inserted here as they were ocean-going steamers which had Bombay as their port of departure. The "Caledonia" and "Peninsular" were doubtful cases, as both recovered, and the diagnosis was not confirmed by the bacteriological examination which was made. This leaves only one genuine case, viz., that on the Booldana" at Rangoon, which developed plague after leaving this port during the year 1899. Besides the above-mentioned ships it is only reasonable to suppose that some of the coasting vessels must have conveyed plague cases to Karáchi, and the small ports north and south of Bombay; but on the whole they must have been comparatively very few, more especially when the large passenger traffic which exists between these ports is taken into consideration. The coast ports south of Bombay to which the majority of the local passengers go are free from plague. Karáchi and Cutch-Mandvi are the only ports on the coast north of Bombay which are infected, and the disease is said not to have left them since the first outbreak in 1896.

Whenever any of the crew or passengers, who were prevented from sailing on a vessel bound for a foreign port developed plague, the fact was communicated to Government with a view to telegraphic intimation being given to the authorities at the first port of call. In cases where plague occurred among persons prevented from sailing on vessels bound to an Indian port, the fact was notified by the Port Health Officer to the next port at which the vessel was due to call.

During the year 117 cases of plague were prevented from proceeding on vessels leaving the port; 34 cases were found on vessels and native craft in the harbour, and at the docks and bandars, and four were found on vessels coming from infected ports close to Bombay, making a total of 155 plague cases.

Towards the end of the year 1898 the Indian Plague Commission was appointed. The members inspected the work of the Port Health Staff, and took evidence on the measures adopted at this port for the prevention of the spread of plague by sea. Their report has not yet been issued, but at the time of their inspection they expressed themselves as being thoroughly satisfied with what was being done to prevent the spread of plague to foreign countries.

Unfortunately plague has broken out at foreign ports, but so far no country or port can point to Bombay as being the cause of the plague from which they are suffering; at least, in no case can outbreaks at foreign ports be traced to the crew or passengers from Bombay. The question of infection by rats and cargo has not been touched on, as presumably the subject will be fully dealt with in the report of the Indian Plague Commission.

It is probable that plague of a mild type has been and is widely distributed in the East, and when at times it broke out as a mild epidemic, the high mortality was attributed to an unhealthy season or year. At present every one is on the look out for plague with the result that the true cause of the high mortality which occurrs from time to time is recognised as being due to plague. I may mention that plague is endemic on the Arabian Coast of the Red Sea between Leith and Lohea, and that, owing to the recurrent epidemics in October 1893, July 1894, August 1895 and October 1896, quarantine was imposed at Suez and Aden against arrivals from the infected part of the Arabian Coast.

The majority of plague cases in the East contract the disease by inoculation through cracks, fissures or ulcers on the feet as the large majority of the population go barefoot. It is, therefore, probable that so long as plague in the East is confined to the bubonic type the people at European ports and at other ports where the population wear boots and shoes, will not suffer from the disease in an epidemic form.

ABSTRACT OF THE REPORT OF THE CALCUTTA MUNICIPALITY FOR 1899-1900.

(*W. R. Bright, Esq., Chairman of the Corporation.*)

Town and Bustee Improvement.—The total expenditure on account of town and bustee improvements during the year 1899–1900 was £5,626 against £6,642 in the previous year.

Water Works: Filtered System.—The average daily consumption of water for the year under report amounted to 20,681,822 gallons as compared with 20,684,393 gallons in 1898–99. 1,337 feet of 4-inch pipes with 2-4 inch sluice-valves and 725 feet of 3-inch pipes with one 3-inch sluce-valve were laid in Penn Estate and Little Rawdon Street respectively. For the improvement of water-supply in Hastings the existing small pipes in the streets of the village of Hastings have been taken up to a length of 5,125 feet, and replaced by 6,729 feet of new pipes of larger size. Besides, the above six standposts have been fixed—four in town area and two in added area. The total mileage on the 31st March, 1900 was 315·16 miles. The number of premises connected during the year amounted to 610, or the total number on the 31st March, 1900, 28,953.

The consumption of filtered water per head of population per day was 33·68 gallons in the town area and 20·89 gallons in the south added area.

Unfiltered Water Supply System.—The average quantity of unfiltered water supplied daily was 9,687,493 gallons as compared with 4,778,899 gallons in 1898-99, and the consumption per head of population per day was 17·52 gallons in town area and 3·69 gallons in south added area.

The number of premises connected for flushing, &c., purposes and street-adjuncts in connection with the unfiltered water supply system on the 31st March, 1900, are 2,835 premises, 121 public conveniences, 2 bathing-platforms, 345 sewer-flushings, and 5,650 ground-hydrants. 63,526 lineal feet, or 12·03 miles of pipes, have been laid, and 607 ground-hydrants for piping sewered roads in town area. Besides the above, 2,789 feet of 14-inch and 639 feet of 12-inch pipes were laid, and one 14-inch and four 4-inch sluice-valves and 33 ground-hydrants were fixed departmentally in connection with the supply of unfiltered water to Palmer's Bridge Pumping Station and High-Level-Sewer.

The total length of unfiltered water pipe laid in the south added area now totals 191,307 feet, or 37·55 miles. Water is daily pumped into the district and is used for road-watering purposes. The unfiltered water will now be used in place of filtered water for the watering of gardens, &c., wherever possible.

Drainage and General Construction.—During the year 4·09 miles of pipe-sewers were entirely re-constructed to new specification, ·27 mile of surface drain was constructed and ·91 mile of kerb and channel stones was laid in public streets and 1·5 miles of brick sewers were repaired, 30 sewer man-holes, 13 sewer lamp-holes, 18 gully-pits and 37 flushing-chambors fitted with automatic flushing syphons were constructed. The sewer, including 9·46 miles of bustee sewers, now measure 200·680 miles.

Of works of public convenience 14 double-seated Bombay pattern urinals with "Finnimore" patent seats have been erected and brought into use, five old bathing-platforms, four night-soil depôts, one methers' barrack and one urinal have been thoroughly repaired. One new bathing-platform is under construction.

Three hundred and thirty-one thousand two hundred tons of refuse were conveyed by the municipal railway to the square mile and unloaded, as compared with 308,110 tons in the previous year. In addition to this, 16,913½ tons of road metal and building materials were hauled from the store depôt at Baugbazar and unloaded at the various sub-depôts in Circular Road.

House Drainage.—The number of premises connected with the public sewer during the year was 502, bringing the total up to 30,670. The drains of 6,096 premises were inspected during the year, and out of this number 1,695, or 27·8 per cent. were found more or less defective, and notices to rectify, specifying the defects were issued in all cases ; 7,535 re-inspections were also made.

Sanction was accorded to the connection of 789 privies with the public sewers.

Health of the Town.—The year under review has been a specially unhealthy one, the death-rate being the highest recorded during the past 10 years except 1895. The mortality from dysentery and diarrhœa was higher than that of every year since 1889 ; and though the mortality registered under the head of fever was lower than that of the previous eight years excepting 1898, the fall was more apparent than real, as in consequence of the presence of plague in the town cases of fever were often registered under other causes, and the mortality registered under causes other than small-pox, cholera, bowel-complaints, fever and plague, was the highest recorded during the past 10 years. Deaths from cholera and small-pox, however, were fewer than the average of the past 10 years. The birth-rate, though showing a considerable increase over the previous year, was still lower than the average.

A sketch is given in the Health Officer's Report of the presence of larval and pupal forms of mosquitos of the anopheles type, which are thought to form a link in the transmission of malaria from man to man, in a large number of the tanks and *dobas* in Calcutta, and of the experimental measures taken for their destruction.

The number of vaccinations during the year was 16,011 against 13,255 in the previous year. The Health Officer's scheme for the re-organisation of the Vaccination Department of the town was sanctioned during the year, but owing to the inadequacy of the grant for the purpose, and other causes, the scheme could only be partially carried out.

Samples of the filtered water supplied to the city were analysed, as well as samples of river water and water drawn from settling tanks at Pulta. The results were satisfactory though there was a rise in the temporary hardness of the filtered water. Samples of water from foul tanks and wells, as well as of milk, *ghee* and other articles of food were also analysed, and the illuminating gas supplied to the city was periodically examined. A fair amount of bacteriological work was also done.

Rice and *dal*, the common food of the poor, were cheaper than last year.

Articles of food and drugs were inspected, and over 2,735 maunds of grains, vegetables, etc., were condemed as unwholesome and destroyed. Over 105 maunds of meat found unwholesome at the municipal slaughter-house were likewise destroyed.

The number of animals slaughtered rose from 151,494 in 1898–99 to 169,993 during the year under review.

In the municipal gowkhanas the mortality of animals exceeded that of last year. There were 617 deaths, of which 209 were due to rinderpest, 207 to general debility and 98 to glanders and farcy. The Health Officer has made proposals for reducing the mortality which are engaging the attention of the Commissioners.

Thirty-two thousand nine hundred and thirty-three waggon-loads of refuse, etc., were removed from the town and a part of the suburbs and sent to the Square-mile. This figure is the highest yet recorded. The rest of the refuse in the suburbs was collected and otherwise disposed of.

Twenty new waggons for the removal of refuse have been sanctioned, and the number of inspectors to supervise waggon-loading work has been raised from one to five.

The number of tanks filled up during the year was less than in the previous year (40 against 45), but the number of prosecutions in the owners of insanitary tanks was much larger (282 against 32).

ABSTRACT OF THE REPORT OF THE HEALTH OFFICER OF CALCUTTA FOR 1899.

(*Dr. J. Nield Cook.*)

Except for plague, which persisted with a low degree of epidemicity throughout nearly the whole year, the health of Calcutta was comparatively good, the deaths registered under all the special causes, cholera, diarrhœa and dysentery, small-pox and fevers being 1,852 below the average of the previous ten years. The excess above the normal mortality may therefore be directly attributed to plague, and this is graphically shown in the chart at the beginning of the report, in which the plague mortality and the general mortality are represented together. Plague was under a separate department consisting of Major H. E. Deane, R.A.M.C., and a number of European and other Medical Officers who had a separate Office, and worked independently of the Health Department, so as I took no part in its administration I am unable to report on it. The system of having separate staffs and disinfecting establishments for different epidemic diseases besides being costly has decided drawbacks, for many letters giving information about plague cases are addressed to the Health Officer, and time is lost in transferring them ; many of these letters deal partly with plague and partly with sanitary matters and in cases which are wrongly reported in the first instance two inquiries have to be made—one by the plague officers and the other by the medical officers of the Health Department.

The comparative mortality ratios for different parts of the town are not reliable as the populations of the wards given in the census of 1891 are very far from being correct. It is hoped that next year, when the new census figures should be available, it will be possible to make more accurate statements and reliable deductions, though so long as no death certificate of any kind is required and our information of the causes of death depends upon the statements of illiterate persons interpreted by Registrars with only a modicum of education our information as regards the mortality from special diseases must be practically useless.

Meteorological Conditions.—There was no marked variations from the normal in the meteorological conditions, which do not appear to have exercised more than a general seasonal influence on the health of the town. In the first quarter the mean temperature averaged 71·8° F. against 73·5° F. the rainfall was 2·35 inches below the average, humidity slightly above and barometric pressure slightly below. In the second quarter the mean temperature was half a degree below normal, the rainfall 9·06 inches above the average, the heaviest fall occuring in June, the humidity was 4·6° above and the barometric pressures slightly above normal. In the third quarter the temperature was practically normal, the rainfall 2·35 inches above the average, the heaviest fall occurring in July, namely, 21·47 inches, the rainfall during the remainder of the quarter being below the average, and the humidity and barometric pressure were slightly above normal. In the fourth quarter the temperature was well below the normal, especially in November and December, averaging 71·6° F. against 76·1° F., the rainfall was below normal, being 3·04 inches against 6·5, the humidity averaged 4° above normal, and the barometric pressure was slightly above normal.

Price of Food.—Butcher's meat was on the whole cheaper than it has been in previous years, ghee was the same price, and rice and dhal were cheaper, firewood being dearer. Common rice, the best index of the food of the poor, sold for from As. 2-0 per seer, the average price being As. 2-6 to As. 2-9., a very appreciable reduction.

Vital Statistics: Births.—The total number of births registered in Calcutta was 11,004 giving a birth-rate of 16·1 against 9,530 and 13·9 in the previous year. The low birth-rates in Calcutta are ascribed to the population being to a considerable extent a floating one, and to the female population being comparatively small. The proportion of male to female births was 108 to 100. The Christian population was the most prolific with a birth-rate of 20·7 per 1,000 of the population, the Hindus coming next with 16·7 and the Mahomedans last with 13·6.

The number of still-births was 933 against 729 in the preceding year, being 84·7 per 1,000 live births. This figure is so high that I can only suppose that numbers of deaths are entered under this head that should rightly come under infantile mortality.

General Mortality.—The number of deaths was 25,823, against 23,343 in the preceding year, giving a death-rate of 37·8 against 29·8, the average of the previous five years being

31·9. The excess above the average number of deaths may be attributed to plague which accounted for 2,332 according to the reports made by the plague officers which number would appear to be below the actual as the number of deaths registered under most of the special heads, such as cholera, small-pox and fevers was appreciably below the average. The mortality varied from 14·7 in Waterloo Street to 47·5 in Burtollah, which had also the highest birth-rate. The mortality in the suburbs was higher than in the town. Particulars of the different wards are given in the statement below.

According to Age.—The mortality was higher under every age period than in the previous year. The mortality under 10 years was higher in the town than in suburbs, but over 10 and under 60 it was higher in the suburbs than in the town.

The deaths of infants under one year of age numbered 4,037, giving a ratio of 366·8 to every 1,000 children born during the year against 368·5 in the previous year. The Mahomedan ratio 504·3 was the highest, though lower than the previous year. Excluding "other classes" the Hindu ratio 334·7 was the next highest, whilst the Christian returns give the comparatively low figure 174·4. As, generally speaking, there is not much to choose between the conditions of life of Mahomedans, Hindus and Christians in Calcutta, it is evident that there is a very considerable infant mortality amongst the two former classes that might be prevented by better care of the infants, apart from the influence of bad sanitation, which affects all classes equally. It is probable that there is some connection between the marriage customs of the classes and their infantile mortality, as when an immature woman marries she frequently bears one or two weakly children.

The incidence of mortality was far heavier amongst females (45·6) than amongst males (33·8) at all ages over one year, and this was due to the heavy female mortality in the town as distinguished from the suburbs. There is nothing to show whether this mortality fell heavier on the *purdah* women or the cooley classes, and excepting marriage and child-bearing, which do not affect the earlier ages it is not apparent why the female mortality in the town is so much heavier than the male. It may be that the female population is underestimated, in which case the heavier incidence of mortality amongst the females would be apparent rather than real. The new census will perhaps clear up this point: at present there are many reasons for doubting that the populations we are working with are even approximately correct.

If "other classes" of which the members are comparatively small be excluded, the Hindus had the highest mortality (38·8), and the Christians the lowest (24·9).

The following statement shows that the mortality was above the average of the previous five years in all the wards of the town and suburbs except Waterloo Street and Bamun in the former, and Sukea's Street, Tallygunge and Ballygunge in the latter. Cholera was worst in the Added Area, Shampuker and Bhowanipur in the suburbs, plague in Burtollah, Jorabagan, Jorasanko and Burra Bazar; fevers in Hastings and Entally; and dysentery and diarrhœa in the Added Area, Burtollah, Sukea's Street, and Moochipara, and in Entally and Kidderpore. The total registered mortality from cholera, small-pox and fevers was however below the mean in both the town and suburbs, that from dysentery and diarrhœa being above the mean in both.

Special Causes of Mortality: Fevers.—The total mortality registered under this head in the town and suburbs combined was 7,173, against 6,060 in the previous year, and 8,189 the average of the decade. The comparative incidence in different parts of the town is shown in shades of colour on the map at the beginning of the report. Though the registered mortality from fevers was below the average, I believe that this does not truly represent the fever mortality for the year; for the deaths registered under other causes were 3,223 above the average, and I have shown in the previous report that with the advent of plague the deaths registered under fevers fell appreciably, whilst there was a corresponding rise in deaths registered under "other causes." Moreover, the surgeon to the police, the officers of the native regiment, private practitioners, and natives who knew the town well, all assured me that fevers were unusually prevalent and severe in type. The largest number of deaths registered as fevers occurred between the middle of February and the middle of April, a very dry and hot season when malarial fevers would not be expected to be especially prevalent. But as the heaviest plague mortality occurred about this time, it appears probable that a number of plague deaths were registered as fever, though as I have already stated many of the ordinary fever deaths were registered under "other causes" to avoid the suspicion of their being due to plague. But the registration of the causes of death in Calcutta is so unreliable that it is difficult, if not impossible, to draw reliable inferences from the statistics, especially as I have strong grounds for believing that the census figures of 1891 are far from being a true index of the relative population of different parts of the town at the present time.

Mosquitoes and Malaria.—Being convinced that mosquitoes of the anopheles type form a link in the transmission of malaria from man to man, though the exact nature of the connection may not yet be fully understood, it seemed to me that the time had come to give practical effect to what have hitherto been more or less theoretical considerations, and try whether anything could be done to reduce the very heavy mortality from fevers, which appears with but little variation in the death returns of Calcutta, and that, if my efforts in this direction were to meet with any measure of success, this would in itself be the strongest confirmation of the truth and value to scientific medicine of the mosquito theory. Accordingly, in 1899 I applied to the Commissioners for permission to employ Mahomed Bux (who as peon to Major Ronald Ross used to hunt for anopheles mosquitoes for his work when he was in Calcutta) on Rs. 16 per mensen, and an assistant on Rs. 8 to hunt out the places where these mosquitoes bred within the area of the municipality, and, if possible, to kill them in the larval or pupal stage of their existence. The Commissioners sanctioned the project for one year in January, 1900, with the condition that the total expenditure should not exceed Rs. 30, or £2, a month, and Mahomed Bux took up his appointment on the 15th February, 1900. The first thing to be done was to ascertain the breeding-grounds of the anopheles mosquito. The practice adopted was for Mahomed Bux and his assistant to do the hunting and bring specimens, and for the Assistant Health Officer, Dr. Sen, and myself to verify his results, and mark the places on a map with a short note. Up to the time of writing, three months from the commencement of work, we have found 89 such places. I had intended to send Mahomed Bux round with my Sanitary Inspectors, so that they might all learn how to recognise anopheles larva, and be able to report the places where it was found, but owing to the prevalence of plague, cholera, and small-pox, their work was exceptionally heavy, and I thought it better not to employ them on work that might take them away from their more legitimate duties. The survey was made during the driest and hottest part of the year, when mosquitoes die off very quickly, if they are bred artificially, so that it is probable that the number of breeding-places which we found is much less than it would be during the rains, and owing to the short time and small number of workers it is probable that the survey was not quite complete. The places are indicated by a red spot on the map at the beginning of the report.

Most of the places are tanks. These are not the large well-made tanks containing comparatively clean water, for in such I have never found anopheles larva, but small tanks generally containing rather foul water and often a fair amount of low vegetation, more or less corresponding with the duck ponds to be seen on village greens in England. Many of the anopheles tanks contained quantities of fish and tadpoles, but in the majority of these the anopheles larva was not plentiful, except perhaps in a corner shut off by floating bamboos thrown into the water to soak. So it appears probable that they do feed on them and keep down the numbers if they have no other food that they prefer, though they do not as a rule entirely prevent their breeding. It is more usual to find anopheles on the leeward than the windward side of a tank. They are not generally found in the filthiest tanks containing practically sewage and teeming with low forms of animal life.

Anopheles were not usually found in drains, containing sewage, which formed breeding grounds for some of the varieties of culex, but in some instances they were found in stagnant ditches which contained the waste water from stand-pipes. One place that was found to swarm with them was a masonry tank about 12 feet square and 2½ feet deep which was newly made to soak bricks in. Excavations in the ground containing water contained large quantities of larva, more so than and other places, evidently forming the most favourable breeding grounds, but as the search was made in dry weather most of these were dried up. Excavations in tanks which had been de-watered for the purpose of deepening them were found to contain the larva plentifully. It will be seen from the map that the town proper contained only a very few breeding places for anopheles on the extreme north. This is attributed to most of the filthy tanks having been filled up or improved. There is a fringe of red spots to the east of the Circular Road, which has always been considered one of the most feverish parts of the town. There is also a group in Bhowanipur and another in Kasapara on the south of the town. Hastings, Ward 18, is shown to have a very high fever mortality, but contains only one large tank containing clean water, in which I found no anopheles or other mosquito larva. I investigated this and found that the blocks to which the heavy rates from fever and all cases were ascribed were not inhabited by regular residents of Calcutta but by military men and followers of the Transport Service and that the population had been vastly under-estimated. Block I of the census report, which is occupied by barracks, has a death-rate from fevers 124·0 and from all causes of 262·7 per 1,000 per annum, which must have attracted notice if it had occurred. A block close by, which is mostly bustee, has a death-rate from fevers of 10·35 and a total death-rate of 20 per 1,000 per annum. When a population mainly consisting of selected young adults who have passed a medical examination for admission to the army is shown to have an almost unprecedented mortality and a poor bustee population of all ages living in huts in the immediate neighbourhood to have only a fraction of that mortality, it is tolerably evident that there is something wrong with the figures. The following statistics of the population fever mortality and general mortality of Hastings, block by block, show this clearly :—

Census blocks.	General character.	Census population of 1891.	Average deaths from fevers for five years.	Ratios of fever mortality.	Average total deaths for five years.	Ratios of mortality for five years.
Block 1 ...	Barracks and Offices ...	137	17	124·0	36	262·7
„ 2 ...	Good Residential Quarter ...	605	9	140·8	25	41·3
„ 3 ...	Poor bustee people connected with the river.	2,126	22	1·3	46	21·6
„ 4 ...	Mainly bustee	598	3	5·0	12	20·0
„ 5 ...	Transport lines	979	12	12·2	31	31·6
„ 6 ...	Mostly bustee	375	10	26·6	28	74·6

So far I have found no anopheles larva in the water on paddy-fields though I have walked over many miles of them. Captain S. P. James, I.M.S., however, found the rice fields round Quilon to be the principal breeding ground. I have found none in wells though I have not examined very many : I have found other varieties of mosquito breeding in them. Mahomed Bux informed me that Major Ross found them in two wells in Bhowanipur, but when I went to examine them I found that they had been filled up. In many places where anopheles larva was found it could not be seen with the naked eye, but when a tin dipper and a porcelain dish were used they could be seen. This was either because they were very small not being full grown, or because there were not many of them ; sometimes only one or two would be obtained in several dips.

Some experiments were tried in the extermination of anopheles larva. It was found that they could be quickly killed in pools with kerosine oil, but re-appeared again in about a week. So if they were confined to small pools and the breeding places were not too numerous their extermination would not be a very difficult matter. Most of them could be killed off by kerosining the pools every few days and the pools filled up or drained. The tanks, however, present much greater difficulties, as it is difficult to cover the surface of even a small tank that contains much vegetation with kerosine. Our experiments in this direction were by no means a success. I did not try crysanthemum or any of the

other mosquito larvicides. Though the difficulties are very great I do not think they are insuperable. Much good would probably be affected by filling up or improving the foul tanks in which anopheles breed. It is doubtful whether tanks of the better class contain enough pabulum for their sustenance: it must be remembered that the male mosquito is not a blood-sucker and has to obtain sufficient sustenance in the larval state to last him his life-time. Another important point is that mosquitoes do not generally travel far from their breeding-places but sit tight under shelter when the wind is strong, so, though anopheles mosquitoes are very prevalent on the other side of the canal on the east, if they were once exterminated in the town it is doubtful whether they would come in from outside to any extent. All things considered it does not appear probable that any appreciable effect can be made on the prevalence of malarial fevers in Calcutta with an expenditure of Rs. 30 (about £1) a month including the pay of establishment, though that has been found to be sufficient for a preliminary investigation into the prevalence of anopheles.

Cholera.—The mortality from cholera, though above that of the preceding year, was much below the average of the previous five years. The number of deaths was 990 against 665 in 1898 and against 2,051, the average of the previous five years, giving a death-rate of 1·45 against 0·97 and 3·00, respectively. The figures for the Towns and Suburbs are as follows :—

——	1894.	1895.	1896.	1897.	1898.	Average of five years.	1899.
Town	1,118	1,302	2,377	1,543	457	1,359	648
Suburbs	577	797	1,072	806	208	692	342
Total	1,695	2,099	3,449	2,349	665	2,051	990

The mortality according to season varied as follows :—

January.	February.	March.	April.	May.	June.
165	85	83	67	125	30
July.	**August.**	**September.**	**October.**	**November.**	**December.**
141	39	10	42	68	145

The unusually large number of deaths during May is attributable to a larger number of deaths among Mahomedans about the time of the *Mohurrum* festival; and the excessive mortality during July was due to the influx of large numbers of pilgrims returning from Puri, where cholera was present in an epidemic form at the time.

The mortality varied likewise according to locality, the largest number of cases being recorded in wards Bhowanipur, Jorabagan, Shampooker, Colootola, Coomartooli, and Jorasanko, with 118, 83, 80, 65, 64, and 61 deaths, respectively.

Of the total of 990 fatal cases, 107, or 10·8 per cent. were imported from places beyond the limits of Calcutta, 101, or 10·2 per cent., were pilgrims on their way home from Puri, and 51, or 5·1 per cent., had visited Kalighat to offer sacrifices immediately before attack; and 201 cases had made use of the Hooghly river water, and 35 of the water of local tanks for domestic purposes shortly before they were attacked by cholera. The cases were mainly isolated ones, occurring singly in the majority of instances. In a few places two or more cases occurred in the same localities, which might be considered small outbreaks.

In connection with cholera cases which occurred in the town, 244 samples of water from the Hooghly river, Circular Canal, Tolly's Nullah, and local tanks, wells, bathing-platforms and filtered water supply, as well as of milk and other articles of food were tested bacteriologically for the detection of *comma bacilli*, and in five samples of tank water *commas* were

detected. It is, moreover, worthy of note that a sample of water from a tank at Puri received from the Sanitary Commissioner for Bengal was similarly examined, and was found to contain *commas*.

Small-pox.—The mortality from small-pox was below that of each of the previous five years. The number of deaths registered was 64, against 85 in 1898, and against 588, the average of the preceding five years, giving a death-rate of 0·09 against 0·12 and 0·86, respectively, per thousand of the population per annum.

The outbreak commenced with one fatal case in November and seven cases with two deaths in December, 1898, continued during the first half of 1899, reaching its maximum in March, then after an interval of two months during which no fatal case occurred, recommenced in September and got worse towards the close of the last quarter.

The mortality varied much according to locality. The whole of Shampuker, the Added Areas of Burtolla and Sukea's Street, as well as all Bowbazar, Bamunbusti, Hastings, Baniapooker, Ballygunge and Alipur were entirely free from the disease throughout the year; and though two cases occurred in the Town Area of Sukea's Street, one in Park Street and one in Bhowanipur, they all recovered and did not lead to other cases.

The wards which had the largest number of deaths from small-pox were Watgunge, Colootola, Moochipara, Entally and Puddopooker, with 25, nine, six, six, and four deaths, respectively. The cases in Watgunge all took place during the first six months of the year, while those in Colootola, Moochipara and Puddopooker occurred during the last four months of the year. The cases that took place in Entally, on the other hand, occurred at two different periods with an interval of several months between, namely, four in March and April, and two in November and December.

It is worthy of note that a total of 138 cases of small-pox came to notice during the year, of which 64, or 46·3 per cent., ended fatally, and that the wards which had the greatest number of cases were the same as had most deaths, namely, Watgunge with 44 cases, Colootola with 27 cases, Moochipara with 16 cases, Entally with 15 cases, and Puddopooka with 6 cases. To this list, however, Jorasanko has to be added, with seven cases of which only one died.

Vaccination.—The total number of persons vaccinated during the year was 16,011, against 13,255 in the previous year. Of these 13,394 were primary and 2,617 were re-vaccinations, against 11,569 and 1,686, respectively, in 1898, thus showing an increase of 1,825 primary operations, and 931 re-vaccinations. The increase was mainly due to the presence of small-pox in the city during the greater part of the year.

Of the 13,394 primary vaccinations 12,674, or 94·62 per cent., were successful, 440, or 3·28 per cent., were unsuccessful, and in 280, or 2·09 per cent., the result could not be ascertained. The rate of success calculated on the ascertained cases was 96·64 against 99·07 in the previous year. Of the 2,617 re-vaccinations 532, or 20·32 per cent., were successful, and in 1,117, or 42·68 per cent., the result could not be ascertained. If the unknown cases are excluded from the total, the rate of success in the re-vaccinations was 35·46 per cent., against 23·68 in the previous year. The lower percentage of success in primary vaccination as compared with the previous year is attributed to the unsatisfactory character of some of the vaccine received during the year.

Of the total of 16,011 persons vaccinated, 8,855 were males, and 7,156 were females. According to nationality 10,930 were Hindus, 4,456 Mahomedans, 445 Christians and 180 of other classes. Of the 13,994 primary vaccinations, 8,828 were Hindus, 4,128 Mahomedans, 284 Christians and 154 of other classes. 2,548 were under one year, 10,442 were one year and under six years, and 404 were six years and upwards.

Vaccination was performed during the greater part of the year with vaccine obtained direct from vaccinated calves received from the Animal Vaccination Depôt in Calcutta, or with lanoline paste obtained from the same source. In the latter part of the year, however, in consequence of an outbreak of rinderpest among the calves the vaccine supply from that depôt failed from the 20th November to the 3rd December; and from the 4th to the 17th December the supply was insufficient. In consequence of this some lanoline paste was obtained through the Sanitary Commissioner from the Animal Vaccination Depôt at Darjeeling; but as the majority of the vaccinations performed with this paste proved unsuccessful, a quantity of glycerised vaccine was procured from Madras. The following table shows the comparative rates of success in primary vaccinations obtained

from the use of calf lymph, lanoline paste, glycerised vaccine and humanised lymph, respectively :—

Particulars.	Calf lymph.	Lanoline paste (from Calcutta Depot).	Lanoline paste (from Darjeeling Depot).	Glycerised vaccine (from Madras).	Humanised lymph.
Total No. vaccinated	4,701	8,152	400	68	73
No. inspected	4,589	8,002	383	67	73
No. successful	4,576	7,925	67	63	43
Rate of success per cent. on ascertained cases	99·71	99·03	17·49	94·03*	58·90

* Some of the tubes were rather old when they were used, which accounts for the comparatively low rate of success.

As stated in the last annual report, a complete scheme for the re-organization and improvement of the Vaccination Department of the town was submitted to the Corporation in the early part of the year under review. It was considered by the General Committee on the 9th June, and adopted with certain modifications.

The following figures show the case mortality among the unprotected compared with that among the vaccinated :—

—	Total No. of cases.	No. of Deaths.	Case mortality rates per cent.
Vaccinated...	42	14	33·33
Unprotected	68	37	54·41
Inoculated	20	10	50·00
Having had natural small-pox	3	—	—
Previous protection unknown	5	3	60·00

Laboratory work.—During the year 1899, 47 samples of river water as pumped into the settling tanks at Pultah, and 47 samples of the same water after settling were partially analysed. Twelve samples of impure river water and 47 samples of filtered water from the town supply were subjected to a fuller analysis. The river water contained on the average less suspended solids in 1899 than in the previous year, the total solids in the water after settling were likewise less than in 1898, and the filters separated less solids. It may be noted that on several occasions mere settling was sufficient to remove all suspended solid impurities, chemical analysis showing no appreciable difference in the water before and after filtration. The filtered water showed a further increase in its total hardness over the preceding year, though the permanent hardness was practically the same as in other years. As the filtered water possessed this character in common with the impure river water, the steady increase in the total hardness which has been observed during the past three years is probably due to some new source from which increasing proportions of earthy salts are coming down the river since 1897, the year of the recent earthquake, The proportion of dissolved chlorides in the filtered water during the first half year was higher than that of the previous year, though much below the figures of 1896 and 1897; and it was observed to be inversely proportional to the rainfall during the first quarter of the year.

Fifty-six samples of tank and well water were examined, and all but five were found to be unfit for domestic use.

The following food-stuffs were examined or analysed :—169 samples of ghee, 135 of milk, 21 of arrowroot, 16 of barley meal, 16 of butter, four of flour and two of tea, and

59 samples of ghee, 81 of milk, 17 of arrowroot, 10 of barley meal and one of butter were found to be adulterated, and four of ghee, and 22 of milk, inferior in quality. Samples of disinfectants and of miscellaneous articles were also tested.

Two hundred and forty-four samples of water, milk, and other articles were tested for *comma bacilli*, but *commas* were defected only in five samples of tank water. A number of samples of blood from suspected cases of enteric fever, sputum from cases of tuberculosis and various specimens and cultures from suspected plague cases were tested by bacteriological methods for the purpose of diagnosis. A case of scarlatina occurring at the Female Orphan Asylum was also investigated.

The illuminating gas-supply of the city was examined photometrically and chemically. Its illuminating power averaged 16 standard candles, and the average pressure of supply was $\frac{8}{10}$ths of an inch. The gas was free from sulphuretted hydrogen, and every 100 cubic feet contained on the average 1·8 grains of ammonia and 2·0 grains of sulphur in the form of compounds other than sulphuretted hydrogen.

ABSTRACT OF THE REPORT OF THE MADRAS MUNICIPALITY FOR 1899-1900.

(*Lieutenant-Colonel G. M. J. Moore, President.*)

Births and Deaths.—The total number of live-births registered during the year 1899 was 18,220, against 18,694 in 1898. The ratio per 1,000 per annum calculated on the census population of 1891 was 40·2, against 41·3 in the previous year. The decrease is without doubt due to the hard times, the price of the staple grains remaining high throughout the year. The number of still-births registered during the year was 253, a proportion of 1·3 still-births to every 100 born alive. The male births numbered 9,336 and the female 8,884, giving a proportion of 105·0 males to 100 females.

According to caste the birth-rate among the Mahomedans was 43·2 per 1,000 ; among the Hindus, 40·1 ; among the Christians, 37·6 ; and among the others 3·3.

Mortality.—During the year 1899 there were 17,248 deaths registered in Madras, giving a death-rate of 38·1 per 1,000, calculated on the census population of 1891, against 20,286, or a ratio of 44·8, in the previous year, the average for the decade being 18,461·6. In 1898 the number of deaths was greater than the births by 1,592 but in 1899 the number of births was greater than the deaths by 972. Of the 17,248 deaths registered, 8,631 occurred among males and 8,617 among females, giving a proportion of 100·1 to 100.

The number of deaths according to nationality was Europeans, 75 ; Eurasians, 375 ; Native Christians, 760, Hindus, 13,878 ; Mahomedans, 2,156 ; and others four. The ratios per 1,000 are 30·4 among Christians, 38·6 among Hindus, 40·5 among Mahomedans and 6·7 among " others " against 36·8, 45·8, 44·5 and 10·0 of the previous year.

During the year under report the number of deaths from fevers was 3,317 against 5,489. This decrease is no longer explicable on the grounds that people avoided reference to fever for fear of inquiries about plague. Either deaths attributed to fever have really for some unknown reason decreased or some other fancy influences the public when naming the cause of death. The deaths from " measles " have fallen very low, *i.e.*, from 775 to 291, while the deaths from " diarrhœa and dysentery " have risen high from 3,302 to 3,520 respectively. But the deaths from small-pox have decreased from 116 to 34 and cholera from 778 to 23. Four deaths occurred from plague.

Statement of Mortality from the prevalent diseases in 1899 *contrasted with that of* 1898.

Years.	Plague.	Small-pox.	Measles.	Fevers.	Dysentery and Diarrhœa.	Cholera.	Total.	Other Causes.	General Total.	Ratio per 1,000.
1898	7	116	775	5,489	3,302	778	10,467	9,819	20,286	44·8
1899	4	34	291	3,317	3,520	23	7,189	10,059	17,248	38·1
Average for 10 previous years.	0·9	52·3	535·9	5,849·2	2,918·7	472·3	9,829·3	8,632·3	18,461·6	40·7

Mosquitos and Malaria.—In connection with the mosquito-malaria problem search was made for the breeding places of anopheles with the view of ascertaining the practicability or otherwise of exterminating the genus from the City limits.

Instead of the very limited distribution that one had been led to expect, the larvae were found to be very widely distributed and were collected in the following spots :—

1st Division ...	No search made.	6th Division ...	Swamp in Brick Kiln Road.
2nd „ ...	An old well.		Paddy Fields.
3rd „ ...	An old well.		Pools of rain water in open land.
4th „ ...	Swamps.	7th „ ...	Old wells.
5th „ ...	An old well.		The Cooum.
6th „ ...	Old wells.	8th „ ...	Old wells. Paddy fields. Swamps.

No very exhaustive search was made, but it may fairly be assumed that it they were found in one well in a division the probabilities are greatly in favour of their being found in other wells also, and the fact that they were found in almost all the likely places that were searched renders it pretty certain that it is only necessary to look to find them in each quarter of Madras. The only indispensable conditions with regard to the presence of anopheles larvae in wells seem to be—

1. That the water should be undisturbed.
2. That it should contain plenty of vegetable matter and floating garbage for them to feed on.
3. The water should not be very salt.

If wells, therefore, are regularly used and kept free from refuse and vegetation, neither anopheles nor any other kind of mosquito can flourish in them.

There is no fact here to militate against Ross's theory or the later dictum of Grassi that without anopheles there can be no malaria. It has long been known that every part of Madras furnishes cases of malaria ; it is now known also that every division of Madras contains spots suitable for the propagation of anopheles, and that anopheles actually exists in the majority of them. The larvae cannot be found with equal facility at all seasons of the year, they seem to be most plentiful during the colder months, that is, after the monsoon. The connection between the quantity of water lying about in swamps, the condition of the paddy fields and the prevalence of mosquitos is obvious. No systematic attempt was made to find the anopheles imago in different parts of the town, but it was casually discovered in the Madras club, in the resident surgeon's quarters, general hospital, and in a bungalow in Nungambakam.

The questions now arise. How can the anopheles mosquito be exterminated on the one hand, and how can the man with malarial parasites in his blood be controlled so that he may not be a danger to the community on the other? The researches of Ross, Grassi, and many others, have established that the most frequent if not the only cause of malaria in the human subject is the bite of the anopheles mosquito, that the mosquito must be previously infested with the malarial parasite obtained from the blood of a malarious patient, that one bite by an infested mosquito is sufficient to convey the disease to a healthy person, that in regions where there are no anopheles there can be no malaria, and that where anopheles exists its bites are innocuous unless it has been able first to bite a person in whose blood the malarial parasite is already flourishing.

Whether the malarial parasite has any existence outside the bodies of men and mosquitos, and how it originally obtained entrance into the one or the other, is still as great a mystery as the origin and spread of all the other microbic and parasitic diseases.

It would appear, then, to all but a few prejudiced individuals, that the mosquito-malarial theory is sufficiently developed to be acted on, and it has become the duty of all Governments and corporate bodies, no less than of individuals, to make every effort to check the spread of this scourge on economic if not on humanitarian grounds.

The answer to the first question presents at first sight difficulties almost insuperable. The larvae to be exterminated are found in old wells in all parts of Madras, in a few swamps, in the Cooum, and, last but not least, in paddy fields. If all the old wells are filled up or kept clean, if the swamps were drained, if a flow of water could be secured in the Cooum, or at any rate it could be kept clean enough to allow the bottom to be seen anywhere, and if wet cultivation were stopped within municipal limits, then anopheles could not exist; and with its disappearance, barring importations, malaria would also die out. To make all these improvements involves the expenditure of large sums of money and the lapse of several years. Endeavours will be made to fill up many useless wells and get owners and occupiers to periodically clean the rest. During the past year a good many have actually been filled, some of which had been found to harbour anopheles.

The swamps known to breed anopheles are four in number :—

(1) North of the Mylapore sewage farm, formed partly by the escape of filtered sewage and partly by the bed of a useless arm of the Buckingham canal at Barber's bridge. This is being filled up with rubbish and in the course of time will cease to exist.

(2) Brick kiln road. A large low lying tract, part of which is always swampy, and the rest swampy for several months after heavy rain. This is slowly being filled with rubbish.

(3) North of Capper House Hotel.

(4) Surrounding the Harness Factory.

The Cooum all round the island, opposite the General Hospital, and opposite Napier Park, was found to provide ample sustenance for millions of anopheles in the months of January and February.

Paddy fields in Egmore, Nungambakam, Kilpauk and Teynampet, were found to be swarming with anopheles. Whether it is practicable or not to stop all wet cultivation within Municipal limits remains to be seen; at any rate there seems to be no particular reason why some of the tanks which irrigate only a few paddy fields should not be breached and used for other purposes. Spur tank, Egmore, is one of these, and there is a double reason for recommending its abolition. In addition to the fact that only half a dozen tiny paddy fields derive any benefit from it, it is one of the places in which dhobies delight to wash the clothes of persons of otherwise cleanly habits; and there can be no question that the quality of the water it contains renders it quite unfit for the purpose. There would be little hardship entailed on anyone by its closure, and the compensation to the paddy fields owners would be but small. Madavakam Tank is another which does not irrigate a large area. When Viyasarpady, Nungambakam, and Mylapore tanks, come to be considered in this light, the question assumes more serious proportions, for the number of paddy fields and gardens which are supplied by the latter especially is very large.

By dealing with all the localities within municipal limits in which anopheles does and can breed, a considerable reduction in their numbers would presumably be effected and though they might still flourish in the paddy fields of Saidapet Taluq they would not be likely to invade the city in large swarms.

Besides filling and cleaning wells, draining and filling swamps, and abolishing wet cultivation within the city limits, other alternative systems of prevention have been suggested, notably that of covering the surfaces of breeding places with films of mineral oil. This of course is not applicable to paddy fields, and practically it is no easy matter to get kerosine oil to spread over the surface of water unless considerably larger quantities than are absolutely necessary are used, and the water is freely agitated. The film, moreover must be constantly renewed as the oil evaporates. If all the available breeding places were regularly oiled no doubt the mosquitos could be prevented from breeding, and, with the exception of visitors from Saidapet, would soon cease to exist: but the expense incurred in purchasing oil and maintaining an efficient staff to properly distribute it would be large, and to be of any use would of necessity be perennial.

The employment of potassium permanganate and other chemicals need not be touched upon, since, as far as is known, they are either ineffectual or their use is attended with grave objections.

The second method of attacking the malaria question, by dealing with those members of the population who are already infested with the parasite, though viewed with favour in Italy, seems in Madras at any rate likely to be unsuccessful. The thousands of natives who at present must be harbouring the parasite could by no means be isolated: and even supposing they were kept apart till they either died or were cured, there would be a continual influx from other parts of the country of infested individuals, who would afford the anopheles fresh opportunities of asserting themselves. Not unless the whole malarious population could be dealt with simultaneously would this method be of any avail. It remains, therefore, to destroy anopheles ruthlessly, wherever discovered, by depriving them of places where they can breed: and though this is within the bounds of possibility within a limited area such as Madras or any other city, it is not easy to see how it can be accomplished over thousands of square miles of a country under wet cultivation. Still, if the number of persons who die from malaria were limited to those who have contracted the disease in the mofussil, a considerable change might be expected in the city fever returns.

Certain accepted dicta concerning the distribution of malaria which are not in accordance with the new theory, required to be substantiated or proved false. It seems to be most unpalatable to many lay minds (medical objections may be neglected, for there are opponents to be found to every theory and rule of practice, be it new or old, and some show of reason usually accompanies such opposition) and is condemned in a breath with vehement and unsupported assertions. It will have to be shortly determined by competent observers whether malaria is endemic in any part of India in which anopheles does not exist, and, conversely, whether anopheles is found in any place in which there is no malaria, and, in the latter case, whether the introduction of a man suffering from malaria can start an epidemic. If anopheles is universally distributed in the paddy fields throughout the Presidency it would appear impossible for any native cultivator to escape periodical attacks. Either anopheles does not so prevail, or the cultivators have become

almost immune, or the type of disease is mild, and does not cause much interference with their daily work, or lead to total disability in the course of years, or there is some other unknown factor inhibiting the extra corporeal propagation of the parasite and rendering the bite of anopheles innocuous. In some old report on the relation between fever and irrigation it is stated that in Tanjore and Trichinopoly, which are freely irrigated by the Kaveri, there is but little fever, while in Bellary, Kurnool and Cuddapah there is little irrigation but much fever. It is not yet known what the relative numbers of anopheles in these districts are. If it be true that malaria has become more prevalent in Madras City during recent years, *i.e.*, since the introduction of pipe water, a statement which, in the face of the known unreliability of all the available statistics, can never be proved, support is derived from the fact that many wells, which formerly were in daily use and were kept clean, are now merely receptacles for garbage and breeding places for mosquitos.

As regards the species of anopheles discovered in Madras there were three only ; one very common and the other two very rare and never found separately from the first. As the common one was many times bred from the larvae, and even from the ova, through the nymphal stage to the perfect insect and carefully compared in each metamorphosis, there can be no doubt upon this point. Whether the specific name of this insect is Claviger or Pictus is not known. Its most obvious characteristic is the four bars visible to the naked eye, formed by the pigmented scales on the costal margin of the wings. The pigmented scales are confined to the costal margin, the costal and subcostal nervures. The other scales showed only a light yellow colouration. In the second species instead of four bars there are two only, the proximal one being about three times as long as the distal. In the third species there are three deeply pigmented bars along the costal margin. All the other scales are also pigmented, but less deeply, with the exception of four rows of unpigmented scales along the costal margin separated from each other by the three pigmented bars.

It remains to collect and classify all the different species of anopheles, if not of culex, in Madras and to determine which of them are capable of transmitting the disease, a work of no little magnitude. Anopheles may or may not live side by side with culex in wells ; in swamps the genera usually occupied different localities and lived apart ; in paddy fields they live apart ; in the Cooum sometimes together and sometimes apart. Though large and voracious culex larvae were often seen to devour newly hatched and delicate anopheles larvae in captivity, it is quite certain that to encourage culex on a large scale in order that it may eat up all the young anopheles, as has been suggested, would not be a desirable experiment. Culex probably only takes to cannibalism when its usual diet fails.

Small-pox.—The total number of deaths registered in 1899 from small-pox was 34 against 116 of the previous year. The small-pox of 1899 was a continuation of that which commenced in the beginning of 1898. The incidence on the vaccinated and unvaccinated is shown in the following table :—

——	Attacks.	Deaths.	Fatality.
Unvaccinated	47	18	38·3
Said to be vaccinated but no marks	27	11	40·7
Vaccinated	28	4	14·3
Had previous attack of small-pox	1	1	100·0
Total	103	34	33·0

——	Total deaths.	Under 10 years.	10-20.	Over 20.
Unvaccinated	18	16	1	1
Vaccinated	4	1	1	2

Cholera.—There was but little cholera during the year. A localised outbreak occurred in the Nungambakam village, the origin of which failed to be traced. The first attack was on May 19th and the last on June 4th. Fifteen cases in all, distributed over nine houses, came to light during that period and nine of them died. All the persons attacked were Sudras, with the exception of one Brahmin and one Pariah. The Sudras were in the habit of drinking water drawn from one well which was first Hankinised on

21st May. The Brahmin used water from another well reserved for that caste, and the Pariah probably obtained water from one of the Sudras. As far as could be ascertained only these two wells were used by the affected persons. Eighteen other wells in the neighbourhood were, for precaution's sake, Hankinised, and the people who used them sent to the taps for their supply. It appeared to be extremely probable that this Sudra well was the means of spreading the infection, but in the absence of any facilities for making a bacteriological examination nothing can finally be known. The condition of the well at any rate, afforded ample opportunities for contamination, as its parapet was broken away and it was situated in the middle of paddy fields, which were both artifically and naturally manured by human excreta, and through which all persons had to pass in order to reach the well. Nothing could then have been easier than for infective material to have been washed off the feet of the water drawers into the well, which as before mentioned had no parapet or platform around it.

After the epidemic had subsided, since this well was temple property, and in some degree sacred, it was not closed, but the owners were compelled to put it into proper repair. The villagers were warned of the danger they ran in drinking water from such wells and two more fountains were erected to supply Red Hills water for their use.

Besides this small outbreak, there were five other deaths from cholera during the year, making 23 in all.

Plague.—During the year four deaths occurred from plague, against seven in the previous year. All of them were imported cases.

Measles.—The number of deaths registered from measles was 291, against 775 in the previous year.

Bowel Complaints.—Under the heads of dysentery and diarrhœa there were 3,000, and 520 deaths registered in 1899, against 2,750 and 552 of 1898.

Infantile Mortality.—There was a visible fall in the rate of infantile mortality during the year under report from 404·2 deaths to every 1,000 births of 1898, to 363·8 deaths to every 1,000 births of 1899. The total number of deaths for the year registered under this head was 4,973, against 5,525 of the previous year.

Vaccination.—The total number of cases vaccinated during the official year 1899–00 was 24,959, against 28,186 in 1898–99, showing a decrease of 3,227 cases. The decrease is due to the less prevalence of small-pox during the year when compared with 1898–99.

Out of 24,959 cases vaccinated, 14,457 were males and 10,502 females. Out of 24,959 vaccinations performed, 22,428 were successful, 1,220 unsuccessful, and 1,311 unknown. The large number of unknown cases was due to the release of the convicts of the Penitentiary undergoing short terms of imprisonment of from three to five days, before the result of the operation could be ascertained. Also to the Natal emigrant coolies who after vaccination were rejected as being physically unfit before they were brought to the Vaccine Depôts for inspection of result.

Out of a total of 24,959 cases vaccinated, 10,013 were brought to the Vaccine Depôts for inspection under Bye-law 5 of the revised bye-laws, dated 22nd February, 1898. The result of 12,749 cases vaccinated excepting the Jail convicts (2,197) were ascertained by the respective Divisional Vaccinators, and the parents who failed to comply with the bye-laws were reminded and warned to take their vaccinated children to the depôts for inspection of the Vaccinator. This procedure was adopted to reduce the number of prosecutions under Bye-law 5. The results of 2,197 cases vaccinated in Her Majesty's Penitentiary were verified by the Deputy Inspector of Vaccination during his weekly visits.

The percentage of success both in Primary and Re-vaccination, excluding the unknown cases from the total was 94·84, showing a decrease of ·95 per cent. below the year 1898–99. The decrease is accounted for to the low percentage of success obtained in re-vaccination, which fell from 83·18 in 1898–99, to 76·36 in 1899–00.

The subjoined table shows the result obtained in both primary and re-vaccination as compared with 1898-99 :—

Year.	Primary Vaccination.				Re-vaccination.			
	Successful.	Percentage.	Unsuccessful.	Unknown.	Successful.	Percentage.	Unsuccessful.	Unknown.
1898-99	20,147	99·48	105	375	4,919	83·18	994	1,646
1899-00	18,722	99·61	73	287	3,706	76·36	1,147	1,024

Of the total vaccinated 1,453 were Europeans, East Indians, and Native Christians, 2,418 Mahomedans, 21,083 Hindus, and five other castes. Out of 24,959 cases vaccinated 19,082 were primary vaccination, against 20,627 in 1898–99, showing a decrease of 1,545 cases. The percentage of success in primary vaccination was 99·61, showing a small increase of 13 per cent. over the previous year. The number of re-vaccinations performed among adults was 5,877, against 7,559 in 1898–99, showing a decrease of 1,682 cases. The percentage of success was 76·36, showing a decrease of 6·82 per cent. below the year 1898–99.

During the year 13,530 infants under one year of age were vaccinated, against 15,643 in the previous year, showing a decrease of 113 cases. The percentage of success obtained in the infantile vaccination was 99·73, against 99·58 in 1898–99, showing a small increase of 15 per cent.

Meteorological Conditions.—The Government Astronomer reports as follows :—"Temperature—was below the average for April, October, and December, normal in January, and above the average for other months. The highest shade temperature recorded was 104°3 F. on the 29th May, and the lowest was 60°1 F. on the 25th January. Rainfall was above the average in April, July, September, and October, and below the average in all other months. The deficiency for the year was 8·02 inches. During October 22·29 inches fell, and the heaviest fall in one day was 2·96 inches on the 23rd of that month. The total fall in November and December was only 1·79 inches."

Plague Measures.—Plague measures this year resolved themselves mainly into the development and supervision of the passport system. No further extensions of existing hospitals or camps were made, and only a few necessary repairs were executed.

Three of the four Plague Officers were recalled to military duty, and the remaining one, Captain Loudon, took charge of the passport offices and prosecutions. The remainder of the sepoys also returned to their regiment in June, 1899.

The English Plague Medical Officers were also one by one removed, the last leaving in December. Reductions were made from time to time in the staffs of the hospitals and camps. Egmore hospital alone has now a sufficient staff to fulfil immediate requirements.

The forecast is still not a bright one, although the feeling appears to be stronger than ever among many people that Madras, by reason of its position on the map, is immune against plague. No doubt it is a comfortable view to take, but likely to lead to difficulties if literally acted upon. No one can definitely assert that plague cannot live here; the most that can be with safety put forward as a working hypothesis is, that the climate is unfavourable to the propagation of the bacilla. Those to whom this hypothesis commends itself tacitly commit themselves to the assumption that cases have actually occurred in the town unknown to the authorities, and that the disease has spontaneously died out without spreading beyond those who brought it from some infected area. It is an established fact that plague does not readily fasten upon a new town; while one importation may be sufficient to start an epidemic, few would deny the possibility of the importation of several cases which might either die or recover in their houses without harming any one else, even so the risk would be great. There is no evidence that such a thing has occurred here, nevertheless the passport system is not infallible, and any day some infected individual might evade its regulations and start a focus of infection in the town.

It is preferable that good fortune has so far saved the town by permitting the discovery of every importation.

Sanitary Defects and Sanitary Progress.—The Mylapore drainage system has continued to work sufficiently well to justify an extension on the same lines into other divisions with a few minor modifications. The fall that could be obtained was not enough to enable the pipes to be self-cleaning, even with the aid of numerous flushing cisterns, and a permanent staff has been employed to drag straw balls systematically from beginning to end of the different branches to keep them clear of silt.

The house connections give some trouble, chiefly on account of the depth and narrowness of the traps, a new pattern of which should be employed in the future. An inconceivable quantity of sand and mud finds its way from the house court yard into these traps, where it is mostly arrested, and unless they are regularly flushed they get blocked up. Cocoa nuts, casual snakes, and other foreign bodies, not unfrequently give rise to more serious obstructions, and a permanent staff has to be maintained to flush these house connections regularly from the outside to clear out the obstructions, and where this cannot be effected, to break the pipe and insert a new one, but the latter course is but rarely necessitated.

In heavy rain, owing to the narrow lumen of the trap and the small size of the overflow hole, the water finds some difficulty in escaping rapidly from the house courtyards, and if a trap gets blocked at the same time, the courtyard remains under water unless the occupier waxes impatient and demolishes the offending house connection with a crowbar.

Another unpleasant experience, suffered by a few of the occupants of certain houses on low ground near the ending of a sewer, was the backing up of sewage through the house connection into the courtyard, which happened when the upper lengths of the sewer on a higher level than the house courtyards were running full as well as the main sewer with which these houses were connected.

The year was spent in discussing the relative qualities of different kinds of pipes for use in the drainage of the rest of the town. Choice eventually fell on the thicker kind of cast iron pipes for the high level main, and on English stone-ware pipes for the sewers and branches. The materials of which the sewer pipes under consideration consisted were glazed earthenware. The difficulty in deciding whether the cheaper cement was strong and durable enough was overcome by a timely discovery in Mylapore. The sewer coolies one day found that one of the recently laid 18″ pipes was obstructed, and on opening up the ground a larger number of cement pipes were seen to be longitudinally cracked. A few intercalated stone-ware pipes were, however, intact. In one place the roots of a tree had insinuated themselves into the cracks and entirely broken up the pipes. The cause of the cracks could not be with certainty determined, but their presence was considered to justify the condemnation of cement pipes.

A point of great importance must not be lost sight of in this connection. Night-soil is now disposed of in four depôts. The carts of Divisions 1, 2, and 3 go to Manally depôt in the North. Here the night-soil is emptied on the surface of the ground, and is at times sold by the rubbish contractor to cultivators. Being far away from human habitations this place does no particular harm, though the smell it gives off at close quarters is probably unequalled.

The carts of Divisions 4, 5, and parts of 6 and 7, go to Brick-kiln road, and their contents are buried in trenches. The ground available is much too small, and is chiefly clay, and therefore the worst that could have been selected. Moreover, it is under water during heavy rains and cannot be used for a few weeks, which leads to great difficulties. The carts of Divison 6, and parts of 5 and 8, go to Stirling's Road trenching ground. This is sufficiently large, and if properly looked after, need cause no offence.

The rest of the carts of 7th and 8th divisions go to Mylapur trenching ground. Here again there is not enough room to carry out the operation satisfactorily and without offence.

As time goes on the difficulties of to-day will tend to increase; there will be better conservancy, more carts, and possibly more people, and therefore more night-soil to dispose of. Trenching, though an extremely satisfactory system in a place where there is only a small population, and when suitable areas of land are available, cannot be recommended in large towns, and must shortly be discontinued partially, if not entirely, in Madras. When the iron high level main is completed, it will be possible to abandon trenching to a great extent, and to establish stations at convenient points along the main where the night-soil carts can come and discharge their contents into chambers connected with the main. By the employment of some agency, such as compressed air, the contents of these chambers could be forced under pressure into the iron main, and the whole would be conveyed with the sewage to the North Black Town Sewage Farm. Since the carts would not have so far to go, they could make more trips in the day, and their number might accordingly be reduced. In the same way many of the public latrines could be so altered that the excreta could be directly flushed into the auxiliary sewers; and there is no reason why any householders, who so desire, should not have some form of water closet in their houses directly connected with the street sewer in place of the disgusting form of latrine which is now almost universally adopted.

The first consignment of iron pipes for the high level main has arrived, and the work of laying them will shortly be begun at the Black Town Sewage Farm.

The water-supply presents the same faults as before, many taps yielding a very muddy supply. Complaints are occasionally made of large numbers of fish being delivered, and everything points to the necessity of cleaning more of the pipes. This should be done little by little whenever a few rupees can be spared.

Nothing has as yet been done with regard to the dhobies. A Committee was appointed early in the year to consider the establishment of a dhoby khana, and select a suitable place, but the matter is still unsettled.

A few further improvements were carried out in private markets, and the new "Moore Market" is steadily rising. It is hoped that it will be opened before Christmas.

Many cattle yard owners were compelled to improve their premises, but they usually do the work in such an unsatisfactory way, and with such bad materials, that it only lasts a few months.

The Committee appointed to report on the question of Infectious Diseases Hospitals came to the conclusion that in the present state of the municipal finances nothing in the shape of a new hospital could be built and maintained, but that when the present stress due to plague has passed, then the buildings now used as plague hospitals might be of service.

Printed definitions and instructions are now issued with all building applications to explain to the builders the meaning of terms used in commenting on the plans they submit. It is ignorance as much as adherence to precedent that influences the construction of new houses.

While there is yet time some definite conclusions should be arrived at with regard to the height or number of storeys that should be permissable in contemplated buildings in different parts of the town. As land grows more valuable and trade concentrates, the tendency is to add to the height of buildings, instead of extending the area they cover. When streets are wide this may be indulged in without much harm, but with narrow streets, such as those of Madras, it will, if allowed to go much further, seriously interfere with proper ventilation. The matter has been given a good deal of attention lately in London and elsewhere; it is easily prevented before the houses are built, but afterwards may gave rise to immense trouble. As a rule, the height of houses should not exceed half the width of the street in populous quarters; height = width of street should be the maximum that could be under any circumstances permitted. This, of course, does not apply to buildings facing open land, or having extensive compounds. It will be found that this limit is already exceeded in many parts of Black Town.

One or two small burial grounds were closed with the sanction of Government, but the most offensive one of all, the sanction for the closure of which was obtained last year, unfortunately still remains in use, since all efforts to acquire another in its place have hitherto been unsuccessful. There is no reason why cremation should not go on at the DeMellow's Road ground, even after burials have been forbidden.

The flushing staff which had been organised in 1897, when strenuous efforts were being made to so improve the cleanliness of the town, that plague might not find a lodgment, had to be dispensed with for want of funds; the same deficiency leading to the departure of the 24 Conservancy Overseers. The latter, no doubt, relieved the Sanitary Overseers to a certain extent, but there was a feeling abroad that the good they did was not commensurate with the sum that was disbursed in wages. Three out of seven Sanitary Inspectors, and ten out of twenty Overseers, now possess bicycles bought from the municipality by monthly instalments. Increased mobility means increased efficiency.

Skin merchants were only given provisional licences for their godowns which are situated in populous localities, and were finally informed that they must shift them before the end of the year to the site allotted in Basin Bridge Road or elsewhere. No applications for plots have so far been received.

The Commissioners were asked by Government to consider the question of death certification. After some desultory discussions, in which the main points were entirely lost sight of, the matter was dismissed as being unnecessary or impracticable. That it is impracticable as far as a large proportion of the native population is concerned no one can doubt, as many die without medical attendance of any description and the certificates that would be furnished by the vadians who attend many more would be worthless for the purposes of statistics. But there are many Europeans practising in the town, and Eurasians and Natives with qualification obtained at the Madras University and elsewhere, not to mention pensioned Hospital Assistants, all of whom, it is maintained, should be registered and bound under penalty to certify the cause of every fatal case they attend, as well as to notify under penalty every case of infectious disease they may hear of. No true estimate can be formed of the number of certificates that would thus be received, but fairly accurate diagnosis of even 20 per cent. of the total fatalities would be of inestimable value. No hardship could possibly be inflicted on anyone by this system, and an annual increase in the number of certificates could surely be anticipated.

ABSTRACT OF THE REPORT OF THE MUNICIPAL COMMISSIONER FOR THE CITY OF BOMBAY FOR 1899-1900.

(*W. L. Harvey, Esq.*)

Public Works.

Special Drainage.—Several works under this head remained unfinished at the close of the year, and some other works were commenced during the year.

Some difficulty was experienced in connection with the laying of the 16-inch main from DeLima Street to Frere Road, as it had to pass under a number of sidings in the Wari Bunder Goods Yard, but these were overcome and the following Resolution, No. 6718, was passed by the Corporation :—"That the Commissioner be informed, with reference to his letter No. 14608, dated the 7th September, 1899, regarding certain sewage mains which have to pass under the Wari Bunder Goods Yard and sidings, and the Masjid and Carnac Bridge sidings of the G. I. P. Railway, that the Corporation approve of his giving an undertaking to the Railway to the effect that should the pipe in or near the Railway crossing burst, causing damage to the line and works or serious detention to traffic, the responsibility of such mishap would be accepted by the municipality, except in the case of any damage to which the Railway Company may have contributed." The work was started, the municipal contractors, Messrs. Richardson and Cruddas, being employed by the Railway Company as their own.

The services of Mr. Santo Crimp, the drainage expert, were obtained for the purpose of reporting on the Drainage of Bombay and advising the Corporation thereon. His report was printed and circulated to the Members of the Corporation about the middle of November.

The machinery at the Air Compressor Station and several Ejector Stations has worked satisfactorily during the year. There was a considerable decrease in the quantity of sewage, due to the deficient rainfall.

Pumping Station at Love Grove, Worli.—The Worthington Engines at this Station worked satisfactorily throughout the year. Fortnightly observations showed the efficiency of the pumps to average 91·76 per cent. The conversion of the old engine house into a shred lifting chamber, office and godown, was efficiently carried out at a total cost of about £1,122.

House Connections.—The streets portions of the House Drainage Connections were partly carried out by contract and partly departmentally. The number of connections made was 1,086, costing about £2,780.

WATER WORKS. *Tansa Lake.*—The rainfall for 1899 was 40·07 inches, that for the two preceding years being 98·68 and 104·82 inches, respectively. The total quantity of water received into the lake was estimated at 12,714 millions of gallons or about 45 per cent. of the total rainfall. One burst on the 48-inch main necessitated the water being shut off for thirty-one hours. Considerable progress has been made with the repairs to the embankments.

Vehar Lake.—The rainfall for 1899 was 35·26 inches, that for the two preceding years being 94·51 and 97·36 inches respectively. The total quantity of rain which fell in the drainage area was about 3,060 millions of gallons ; of this about 1,160 millions of gallons, or 38 per cent., reached the lake, as compared with an available total of nearly 6,000 millions of gallons. Notwithstanding the failure of the monsoon it was not found necessary to restrict the quantity of water drawn from this lake. One burst occurred on the 32-inch main and one on the 24-inch main during the year.

Tulsi Lake.—The rainfall for the year 1899 has been 43·80, representing a total fall of about 1,647 millions of gallons ; of this about 356 millions of gallons, or 22 per cent.,

were received into the lake as compared with 111·6 inches in the previous year, yie an available supply of 2,670 millions of gallons, or 62 per cent. There was one bur the 24-inch main causing the water to be shut off for about 12 hours.

Miscellaneous Works.—A 4-inch metered branch for supplying water to the Kut Siding has been made, but no other extensions have been made during the year. revised scheme for the extension of mains has been sanctioned by the Corporation.

Distribution and Maintenance.—The number of bursts on various parts of the sys during the year was 131. The net increase in the number of connections exclusive those made to Health Camps has been 217. The annual growth in the number of conn tions for the past three years has been 0·5, 1·8, and 1·0 per cent. respectively. The work of examination of mains by Deacon's meters shows them to be in a satisfactory condition.

Public Health.—The state of the public health during the year has not been satisfactory. The total mortality for the year under report, exclusive of still-born, was 56,434, being the highest mortality ever recorded for the City of Bombay, the average mortality of the previous five years having been exceeded by 17,785.

On an average 5,775 men and women, 1,124 scavenging and drain carts and 205 night-soil and cesspool carts were at work each day. 344,268·5 tons of garbage, equal to 943·2 tons a day, were collected, removed and disposed of, against 388,816·75 tons of garbage in 1898. 170,506·11 tons of night-soil and cesspool matter, equal to 467·14 tons a day, were collected and removed, as against 169,586·9 in 1898. 167·1 miles of covered drains were opened and cleaned, against 172·1 miles in 1898.

The most noteworthy feature in the work of the Department has been the completion of the scheme for the removal of the city refuse by rail to Deonar and Chembur. The removal is effected twice daily by a train of 25 waggons. The loading of the trains is effected at a loading siding upon municipal land at Mahalaxmi, the refuse being tipped directly from the Health Department carts into the waggons. The system has worked smoothly.

The ground reclaimed by the municipality at the Tardeo Flats has been handed over to the City Improvement Trust. The working of the Garlic Incinerator at the municipal workshops was stopped on the 20th November, 1899, partly on account of complaints against the smoke caused by it, and partly because it stands upon ground claimed by Government.

On the 1st January, 1900, the first step was taken towards improving the system of registration of births and deaths. A District Registrar now resides in each ward and the Deputy Health Officers now perform the duties of the old registrars.

There were 15,796 deaths from Plague, being 2,389 less than in the last year. Plague measures have been carried out by a separate branch of the administration working directly under the Deputy Commissioner for Plague operations.

In addition to the Municipal Dispensary, which was opened in 1898 at Kumbharwada, another was opened on the 22nd January, 1899, at Dongri. They are both free and the attendance has been large.

An Act dealing with the adulteration of ghee came into operation during the year. Several prosecutions were instituted by the Health Officers, resulting in convictions in most instances.

The flushing of house gullies was carried out during the dry weather by means of seven steam flushing engines.

ABSTRACTS OF THE REPORT OF THE ACTING HEALTH OFFICER OF BOMBAY CITY FOR 1899.

(*J. Leask Esq.*)

It would have been better if the late Health Officer, Col. T. S. Weir, I.M.S., had been able to prepare this Report; but as he was recalled by Government to take up a high administrative appointment in the Military Department, he retired from the service of the Municipal Corporation on the 26th of June, 1900, there was therefore no opportunity for him to prepare it before his departure. As I have been appointed to the office temporarily, it is only possible for me to submit a few general remarks, and to compare the mortality and birth statistics with those of the previous years.

The total mortality for the year 1899, exclusive of still-born, was 56,434, the highest mortality which has ever been recorded for the City of Bombay. In 1898 the mortality was 51,961, or 4,473 less than the year under report. Taking the average of the previous five years, the mortality in 1899 was 17,785 more.

The rainfall registered at Colaba Observatory for the year was only 35·90, a little less than half the normal quantity. The heaviest rainfall was registered in June, viz., 20·81. In July the rainfall was only 4·72, in August 5·23, and in September 3·49 inches were registered. The rains practically ceased about the middle of August. The following is the rainfall for the previous three years:—1896, 87·65; 1897, 81·53; 1898, 74·09. From this it will be noticed that there has been a gradual decrease, culminating in the practical failure of the rains in 1899.

The temperature in April, May, June, October and November was high.

The most noteworthy feature in the working of the Health Department has been the completion of the scheme for the removal of the City refuse by rail beyond our boundaries. The Municipality purchased a large area of land at Deonar and Chimbur, having an area of 823 acres, and the refuse is now transported daily by rail to this place. Loading sidings have been constructed upon the municipal land at Mahalaxmi, and here the refuse is tipped from our carts into the railway wagons. At present two trains of 25 wagons each have been run daily.

Registration.—On the 1st of January, 1900, the first step was taken towards the improvement of birth and death registration. Each ward of the City has now resident within its boundary a District Registrar. The Deputy Health Officers now perform the duties of the old Registrars. As has been frequently pointed out in the Annual Reports of the Health Officer, it will not be possible to obtain an accurate system of death registration until the production of a medical certificate of the cause of death is made compulsory. I trust that the necessary amendments in the Law will be made when the new Municipal Act is being considered.

Plague Administration.—Plague measures throughout the year have been carried out under your orders by a separate branch of the Administration, working directly under the Deputy Commissioner for Plague operations. The Health Department have given all the assistance possible to the officers entrusted with this special work in each ward. Men of the Health Department collected great numbers of rats in different parts of the City. They are paid half an anna for each rat. The Port Trustees and the Railway Companies took special measures for the extermination of rats.

Water-supply.—Owing to the deficient rainfall, the lakes supplying the City did not fill as usual, and in consequence the water was not all of good quality, the Tulsi supply in particular being impure. There was much vegetable matter in suspension. The various waters have been subjected to constant and close chemical and bacteriological examination. In January, 1900, it was deemed advisable to issue a public notice about the state of the water, and the people were advised to boil it, as an easy and effective way of purification.

Fevers.—During the year the prevalence in many parts of the town of an in[illegible] type of fever was noticed. Colonel Weir was of opinion that the fever exhi[illegible] symptoms of the type known as "Malta fever," and this view is supported by the opini[illegible] of several local practitioners, under whose observation many of the cases came. The ty[illegible] of fever was different to that usually prevalent in Bombay; the duration of the fever w[illegible] prolonged; there was great pain in the body, and the attack was not amenable to t[illegible] usual treatment. I notice that a similar type of fever has been prevalent at Simla th[illegible] year, and investigations gave results exactly similar to "Malta fever." These obscu[illegible] forms of fever are, apparently, difficult of diagnosis, and their nature could only b[illegible] decided after prolonged enquiry and examination by experts. It may also be noted tha[illegible] in the Thana Collectorate, malarial fevers were much more prevalent than in the previou[illegible] year. Relapsing fever has unfortunately continued throughout the year; and in th[illegible] light of investigations now being carried out by Dr. Cayley and Dr. Christy at th[illegible] Municipal Laboratory at Parel, it is apparent that many of the deaths which have beer[illegible] returned as remittent fever, were in reality relapsing fever. Blood specimens were[illegible] taken from amongst the patients attending the Dongri Dispensary, and microscopica[illegible] examination showed the spirillum of relapsing fever. A serious development of this[illegible] disease occurred in the common jail.

The failure of the rains throughout the Presidency induced abnormal seasonal[illegible] conditions which seriously affected the public health. Fevers and diseases of the bowel[illegible] were abnormally prevalent. Famine conditions in the Mofussil caused the poor to floc[illegible] towards Bombay, and I think there can be no doubt that, irrespective of local conditions[illegible] the increase of population by the incoming of starving people, accounts, in some measure[illegible] for the increased mortality of the year.

Lustig's Serum.—The preparation of Professor Lustig's Plague Serum continued throughout the year at the Municipal Laboratory at Parel, under the able direction of Dr. G. Polverini. The results of the action of the serum will doubtless be dealt with in the report of the working of the Arthur Road Hospital.

Drainage.—So much has been written by the Health Officer in previous Annual Reports, that it would be needless for me to refer at any length to this all-important subject; but I would urge again the necessity for the drainage of Malabar Hill being proceeded with. Many new buildings have been erected on Malabar Hill, and beyond the avoiding of certain of the the old storm-water side gutters, nothing has been done in the way of drainage, and it is possible that the recent prevalence of a peculiar type of fever, which was not confined to one place on the Hill, was connected in some way with conditions arising from polluted soil.

The works in connection with the Mazagon gravitation system of drainage should be carried out with all speed. The cesspool nuisance in Mazagon, which has existed for many years, causing serious danger to the health, and inconvenience, of the people, must continue until drainage connections are made.

Drainage of the northern part of the island, with the extension of population in that direction, will soon become an urgent necessity. Serious nuisances already exist in places owing to absence of drainage, and it is hopeless to attempt to abate these nuisances by the construction of cesspools, and the consequent provision of cesspool carts and an army of cesspool men. Drainage is the only way of relief.

The City Improvement Trust have got a scheme for the opening out of the suburbs to the north of Dadar. It will take years, however, before any scheme could be carried out, and in the meantime the question is, what is to be done in regard to the drainage of this part of the City? It seems to me desirable that a scheme of drainage should be worked out which would fit in with the proposals of the Improvement Trust, as it would be absolutely necessary to have an efficient system of drainage in progress before any extensive building operations take place.

The latrines which have been erected in Colaba are intended to serve groups of houses which have no accommodation of their own, and for which accommodation could not be provided without partial demolition of the buildings. The occupants of these houses made use of public latrines which were erected by the municipality so far back as 1866.

The completion of the Shone system of drainage in Colaba made it possible for the municipality to provide public conveniences of an improved type.

Plague Mortality.—The total number of Plague deaths registered during the year was 15,796, giving a death-rate, on the census population of 1891, of 19·22 per 1,000. In 1898 the mortality from Plague was 18,185 and the death-rate was 22·12. Whether this

n in mortality is only apparent or is really an indication of the gradual cessation e visitation it is impossible to say. Plague has many obscure forms, and it is probable that a large number of deaths attributed to other causes were in reality caused by gue. The city was very full during the year, and I should think the population was ry little short of the normal. As in previous years, the general Hindu community, hich form one-half of the total population, suffered severely, the mortality among this ss being 10,987. There is a notable decrease amongst Jains, Bhatias, Mahomedans d Parsees. Europeans show 12 cases as against 15 of the previous year.

There is a marked reduction in the number of plague deaths occurring in Fort, North, Market, Dhobitalao and Kumbharwada, whereas an increase is shown from Middle and Lower Colaba, Tarwady, Sewri, and Mahim. The increase in Tarwady is due to the fact f there being hospitals and segregation camps in the section. The increase in Mahim is o doubt due to movement of population. The incidence in the other sections shows very ittle difference as compared with last year. Byculla returns 1,440 deaths as against ,432 of the previous year.

A total of 11,026 plague deaths occurred amongst males and 4,770 amongst females, he age-period of males showing the highest death-rate was from 30 to 39 years. Amongst emales the highest death-rate occurred between 10 and 14 and 30 and 34 years.

General Mortality by Causes.—Plague unfortunately again stands the highest, the rate eing 19·22 against 22·12 in the previous year. There is also an increase in phthisis and iseases of the respiratory system, measles and diarrhœa. There was also a considerable ncrease of deaths from fevers. The number of deaths from cholera was 111 as against 104 of the previous year.

TABLE SHOWING THE NUMBER OF DEATHS AND THE DEATH-RATE FROM DIFFERENT CAUSES IN 1899.

Cause of Death.	No. of Deaths.	Death-rate per 1,000 of Population.
Small-pox	440	·53
Measles	1,868	2·27
Fevers	5,063	6·16
Cholera	111	·13
Plague	15,796	19·22
Phthisis	6,029	7·33
Diseases of the Nervous System	3,012	3·66
Do. Respiratory System	8,650	10·52
Diarrhœa	2,529	3·10
Dysentery	1,757	2·13
Accidents	547	·66
All other Causes except Still-born	10,632	12·93
Total	56,434	68·67

Amongst persons born in Bombay 16,522 deaths were recorded during the year, and amongst those born outside Bombay 37,797. This marked difference shows very clearly how varied our population is.

Leaving out Negro-Africans, Buddhists and Lingayets, who form very small communities in the population, low-caste Hindus shows the highest mortality, viz., 131·12 per 1,000. The Jain community, which includes Baniahs also, suffered severely, their death-rate being 75·16. Mussulmans give a death-rate of 73·21, and the general mass of Hindus give a death-rate of 68·95. The death-rate amongst Parsees was 34·89, being considerably lower than in the previous year. The Parsee community, to a great extent, took advantage of inoculation, and the reduction in the death-rate may very probably be due to this. The European death-rate (16·47) was lower than in the previous year. This is remarkable, as it is the lowest death-rate since 1894. I believe there has been an increase in the number of the resident European population within the last few years.

33,340 males and 23,094 females died during the year, excluding those under five years. The highest number of deaths amongst males occurred in the age-period between 30 and 34 years, 3,756 deaths having been registered; and amongst females, 3,479 in the age-period of 60 and over.

The infantile mortality can only be called appalling, a little less than ¼th of t[illegible] mortality being of children under five years of age, and the greatest mortality of any [illegible] is that of infants under one year. The increase in the infant mortality is over 3,00[illegible] more than in the previous year. I think it must be put down in great measure to th[illegible] famine and abnormal conditions which prevailed during the greater portion of the ye[illegible] and the inability of weak and devitalized mothers to afford natural nourishment to the children.

The following are the sections showing the highest mortality:—Mahim, Byculla, Parel 2nd Nagpada, Tardeo, and Kamathipura. The very high incidence in Mahim, 111·13 where there is no crowding of buildings and density of population, can only be attributed to the movements of population, consequent upon plague. Byculla shows a very high death-rate; last year the rate was 88·68, but this year it is 104·97. The densely crowded sections of Bhuleshwar, Khara, Talao, Khumbharwada, Fanaswady, Dhobi Talao and Market show a death-rate ranging from 43·83 to 76·31, leaving out Fort South, which residentially is a small quarter. Walkeshwar has the lowest death-rate, viz., 23·86. In the last annual report Col. Weir has described very fully the causes, viz., over-crowding, imperfect ventilation, and poor living, which exercise the greatest influence on mortality in any of the classes. It is hopeless to prevent over-crowding amongst the poor. Customs of caste, dearness of food, the economic conditions of labour, all tend to induce over-crowding. Over-crowding amongst the poor is not confined to Bombay. It is one of the greatest sanitary problems in all large cities, and is one of the most difficult to deal with in anything like a practical manner. We may hope, however, that the work of opening up the city, now being carried forward by the City Improvement Trust, and the improvement of insanitary buildings now being done by the municipality, will have the most beneficial effect on the general health of the city.

Cholera.—The mortality from cholera was 111, being seven more than last year. The month of highest mortality was March, and Parel and Worli gave the highest number of deaths. Of the total number of deaths, 92 occurred amongst Hindus of other castes. A total of 15 deaths occurred amongst persons who had been resident for three months and under, and eight deaths amongst persons resident for six months and under. The greatest number of deaths occurred amongst persons born outside Bombay.

Fevers.—A total of 5,063 deaths was registered from fevers, being 949 more than in the previous year. As in the last year, remittent fevers claim the highest figures, viz., 4,761, being 1,045 more than last year, but 710 less than the average of the previous five years. To simple continued fever 144 deaths were put down, being 115 less in the last year, and 652 less than the average. Enteric fever shows 44 deaths, being seven more than in the last year, and 11 more than the average. To ague 114 deaths were ascribed, being 12 more than in the last year, but 126 less than the average. I think it is extremely probable that a large proportion of the deaths ascribed to remittent fever were due to plague in some of its obscure forms. It is also probable that some of the cases were due to relapsing fever, which is difficult of diagnosis without microscopical examination of the blood. Taking the fever mortality by months, it rose and fell with the mortality from plague. It rose gradually from January to March, when 762 deaths were registered. March, it being remembered, was the highest month of plague mortality, as well as the highest from all causes. Fevers gradually decreased until June, and then gradually rose right on to the end of the year, 610 deaths being registered in December. The course of fevers during the year ran with practically the same fluctuations as in the previous year. Amongst the Hindus of low-caste there was a considerable increase, the rate being 14·61 as against 6·90 in the previous year. There was also an increase among the general Hindu community. Mussulman mortality was almost the same as in the last year. Parsees showed a slight decline, and Europeans a slight increase. The suburban sections of Parel (12·52), Mahim (11·67) and Worli (11·21) give the highest incidence of fever mortality, Parel section, as in 1898, being the highest. The high fever mortality of the suburbs is no doubt attributable, in a great measure, to the absence of drains to carry off sewage and subsoil water.

To relapsing fever 829 deaths were due, being 283 more than in the previous year, and one-fourth of the number being registered in March. From April the disease rapidly declined, but again rose in December.

Measles.—There was a great increase in the mortality from measles, 1,868 deaths being registered, being 1,614 more than in the last year, and 1,431 in excess of the average of the last five years. As in former years, the greatest number of deaths occurred amongst

Hindus of other castes, and the Hindu low-caste give the highest death-rate. As before, the infant mortality was the highest, and the age period under two years the most fatal. The female death-rate was much higher than that of the male.

Phthisis.—Phthisis again claims a large proportion of the total mortality, 6,029 deaths having been registered, being 405 more than in the previous year, and 1,317 more than the average. The small community of Negro-Africans gives a very high death-rate of 57·53. This community, however, is a fluctuating one. The Mussalman mortality was very high, though a little less than in the previous year. The death-rate amongst Jains and Brahmins was a little lower. Amongst Europeans and Parsees the death-rate was stationary. Only six deaths amongst Europeans were registered. 2nd Nagpada was again the most unhealthy section. Umarkhady was next, and Byculla followed. In the Byculla section there is an increase in the population. The 2nd Nagpada has long been a most unhealthy locality, and it is satisfactory to note that the City Improvement Trust have taken up this district as the first requiring improvement. There died 2,858 males and 3,171 females from this disease. The most fatal period of life amongst males was over 60 years, and amongst females between 30 and 34 years. The female death-rate is nearly double that of the male.

Small-pox.—The deaths from small-pox show an increase, 440 deaths being registered in the year. This was 385 more than in the past year and 117 more than the average. Hindu low-castes suffered the most. There were no deaths amongst Europeans or Jews, and only four deaths amongst Parsees. The section showing the highest mortality from small-pox was Worli, Sewri and Mahim followed. The disease was practically confined to children below the age of five years. It was worst during the first year of life.

General mortality.—From diseases of the digestive system 5,559 deaths were registered, being 957 more than in the last year, and 1,964 more than the average. Diarrhœa and dysentery show a marked increase both as against last year and on the average. There were 3,012 deaths registered under the diseases of the nervous system, being 435 more than in the last year and 725 more than the average. There were 8,650 deaths ascribed to diseases of the respiratory system, being 227 more than the last year, and 2,337 more than the average.

Births.—10,624 living and 1,955 still-born births were registered, being 160 less than in the last year; of these 5,661 were males and 4,963 females. Taking the proportion of males to females, according to the census of 1891, at 170·60 to 100, and assuming that there were 100 females to 100 males, the birth-rate would be equal to 22·04. As explained in the last Annual Report, the birth-rate is affected by plague. It may be noted that the Parsee birth-rate was lower than in the last year, and the Musalmans' rate also shows a decrease.

APPENDIX.

No. 1.

MEMORANDUM by the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER with the GOVERNMENT of INDIA for 1899.

1. According to the report of the Meteorological Department, the rainfall of the whole of India fo the whole year was in defect by 11·14 inches. The season, taken as a whole, was dry and hot. Th rainfall, besides being deficient in quantity, was irregularly distributed. Whilst the fall, mor especially on the eastern side of India, was in some parts in excess, it was greatly in defect i Western India. The exceptional dryness of the year doubtless conduced to lessened sickness o malarial origin.

2. The average strength of the *European Army of India* was 67,697, or less by 44 than in th previous year. Its health, judging from the lower ratios of admissions into hospital, constantly sick deaths, and invaliding, was much better than in 1898. The chief causes of admission into hospita were, again, venereal diseases and ague, although under both heads the returns show a very marked decrease in the year under report as compared with 1898; the admission rate due to ague having fallen from a ratio of 394·0 per thousand of strength to 235·2, and that due to venereal diseases from 362·9 to 313·4. Venereal diseases caused 27 per cent. of the total sickness of the year, and ague 20 per cent., or, between them, 47, as compared with 52 per cent. in 1898. The two chief causes of death were, again, enteric fever and hepatic abscess; the former accounting for 40 per cent. and the latter for 10 per cent. of the total deaths, as compared with 51 per cent. and 8 per cent. in the preceding year. Malarial fevers and venereal diseases, to which the highest ratios of total admissions and total sickness were due, were also the chief causes of invaliding. Of the 2,142 cases of invaliding, 417 were due to secondary syphilis and 229 to ague. As a cause of invaliding "debility" is given the next place with 196 cases. No other disease accounted for as many as one hundred cases of invaliding.

3. Of the four *Commands*, Madras again records the lowest mortality rate, but the highest constantly sick and admission rates. The Punjab Command also again records the highest death-rate, although this has fallen from 27·63 per thousand of average of strength to 14·82, or to nearly half of that recorded in the previous year. Enteric fever, the incidence of which largely determines the relative mortality in the several Commands, was most fatal in the Punjab, and least fatal in the Madras Command; in the former the ratio of deaths ascribed to it was 6·64 per 1,000, and in the latter 3·03, or less than half. Pneumonia and other lung affections were also most fatal in the Punjab, and least fatal in the Madras Command; in the former the death rate from pneumonia was 1·16, and in the latter only 0·16. All of the Commands were healthier than in the previous year.

4. Of the *Geographical groups*, Burma Coast and Burma Inland had death-rates from all causes of 6·63 and 7·82 respectively. These were the lowest recorded. On the other hand, Bengal-Orissa group had a death ratio of 21·87, the highest recorded. The European garrison in each of these three groups was comparatively small, in none of them numbering three thousand men. The Upper Sub-Himalaya group with the largest garrison, numbering upwards of twelve thousand men, recorded a death-rate of 14·12; and the Deccan, with the next largest garrison of close on ten thousand, recorded a death-rate of 9·56. The two groups with the lowest death-rates from all causes had a low mortality from enteric fever; but the Bengal-Orissa group with the highest death-rate records a ratio of only 1·90 from enteric fever; dysentery and hepatic abscess in this latter group accounted, between them, for a mortality ratio of 8·56 As usual, the Western group returns low admission and death rates; its death-rate of 1·86 from enteric fever is the lowest recorded except that for Burma Inland, and its death-rate of 9·31 from all causes is lower than any other, except the rates for Burma Coast and Burma Inland; its admission rate is also the lowest but one. The strength of the garrison of the Western Coast was, however, only 1,611. Too much importance need not be attached to these figures as evidence of the comparative healthiness or unhealthiness of the different groups. The ratios of sickness and mortality recorded for any given group or station might be largely influenced by conditions affecting the men sent to garrison it, such, for example, as their ages and length of service in India, previous exposure on field service, or in camp during epidemics. Obviously, it might be misleading to deduce conclusions regarding the healthiness of geographical groups or stations from ratios of sickness and mortality dependent on conditions not connected with these groups or stations.

5. Of the larger *stations* with garrisons of over 1,000 men, Peshawar, Lucknow, Umballa and Bangalore return the highest death-rates. All of these, except the last, were amongst the stations which recorded the highest death-rates in the previous year. The death-rate of Bangalore, which was only 10·64 in the previous year, has risen to 17·35. Increased mortality from enteric fever had a considerable share in bringing about this result, the death-rate from this disease having risen from 4·26 in 1898 to 7·43 in the year under report. Quetta affords a good example of the influence which

[redacted]c fever may exercise on the death-rate of a station. In previous year's *memorandum* Quetta was [redacted]tioned as one of the large stations recording a high death-rate. In 1898 this rate was 44·43; in [redacted]e year under report it was only 10·30. In the preceding year enteric fever by itself accounted for a [redacted]ath-rate of 35·08, or more than three times the death-rate from all causes in the year under review, [redacted]hen the enteric fever death-rate was only 2·08 per thousand of the strength of the garrison. In [redacted]eshawar the enteric fever death-rate likewise decreased from 24·48 in the preceding year to 9·87 in [redacted]he year under review; and in Umballa from 13·19 in the former year to 8·97 in the latter.

6. Of *regiments*, the 7th Battery, Eastern Division, Royal Garrison Artillery, and the 72nd Battery, Royal Field Artillery, recorded the highest death-rates; the former 71·43 and the latter 68·70 per thousand of strength; but the average annual strength of the one battery was only 14; so that the occurrence in it of a single death gives the high ratio recorded; whilst the strength of the other battery was only 131. The Royal Irish Rifles, with a strength of 716, had 30 deaths, equivalent to a death-rate of 41·90 per thousand of strength. This regiment arrived from Natal on the 16th of April and suffered severely from dysentery, hepatic abscess, intermittent and enteric fevers.

7. Having dealt with sickness and mortality in relation to India, to Commands, to Geographical groups, to Stations, and to Regiments, the Report proceeds to discuss the statistics of some of the chief diseases. Of the three diseases first dealt with, *cholera, small-pox, and influenza*, little need be said. Only a single death was due to each of them. In no previous year have the recorded admission and death-rates from cholera been so low: only one case, a fatal one, of the disease having occurred. Of small-pox there were 14 cases with one death: all the men attacked are stated to have borne vaccination marks. Influenza was the cause of a considerable amount of sickness but of only one death. The total number of cases of this disease during the year was 674; and of these by far the greater number occurred in the months of March, April and May.

8. *Ague* gave rise to just over 20 per cent. of the admissions from all causes: this was less, however, than the percentage in the previous year, when it was 27. The number of deaths ascribed to ague was 19 in each year, but the ratio of deaths was somewhat lower in the year under report than in the preceding year, having been in the former ·28 and in the latter ·30. "The lowness of the ratio was probably connected with the dryness of the year." The Bengal-Orissa group suffered most, and Hill Stations and Western Coast suffered least from ague. In the first of these groups the admission rate was 658·1 per 1,000 of strength, and in the two last 103·6 and 148·4 respectively. *Remittent fever* was much less fatal than in the previous year, only 11 deaths having been attributed to it as compared with 24 in 1898. The exact diagnosis of remittent fever continues to be far from easy. "At Barrackpore cases suspected of being enteric, but not reacting to Widal's test, were returned as remittent fever, even though they did not respond to the exhibition of quinine." In the diagnosis of *simple continued fever*, also, difficulty seems to have been experienced. "Some of the cases were suspected to be enteric fever, or malarious fever, or influenza, or Malta fever, or some yet undifferentiated form." Those who have themselves seen much of fever in India will be the first to acknowledge that, in practice, the differentiation of the several forms of the disease is sometimes a matter of exceeding difficulty, and the larger the experience a medical officer has had of Indian fevers the more tolerant is he likely to be of opinions regarding them which may not coincide with his own. Of the causes of simple continued fever mentioned are sun, heat, over-exertion, want of acclimatisation, especially when these are combined; chill, exposure, constipation, errors in diet and drink. "From 1886 to 1894, while simple continued fever was on the whole falling, ague and enteric fever were on the whole rising." In briefly noticing Malta fever the Sanitary Commissioner issues a word of warning. He says that just at present a number of cases of this description of fever are being discovered in India both among Europeans and natives, and adds:—"but the experience of the past should warn those in authority, while encouraging the research, to exercise a certain amount of reserve in the acceptance of at least the earlier results. After all, serum diagnosis is only in its infancy, or is just emerging therefrom."

9. The returns of *enteric fever* for the year might lead to the expectation that the prevalence and fatality of this disease in the European Army of India had at length received a definite check. In 1898 there were 2,375 admissions and 654 deaths due to it: in the year under report there were 1,392 of the former and 348 of the latter. The admission rate fell from 36·9 to 20·6, and the death ratio from 10·17 to 5·14, a percentage reduction of 44·17 and 49·46 respectively. Had so marked a reduction been the result of the discovery of more effectual methods of preventing enteric fever there might have been room for hope that the reduction would be maintained, or even carried to a lower point in the future. But such hope would be premature. The reason of the reduction "is to be found, perhaps, not so much in the climatic conditions of the year as in the facts that the influx of drafts from England was much smaller than usual, and that there was no field service." Seeing that the liability to die of enteric fever during the first year of residence in India is greater than in any subsequent year, it is evident that, if for any year the supply of drafts of young soldiers from Europe is cut off or reduced, there will be a corresponding reduction in the number of men especially susceptible of contracting the disease. Similarly when, after having been temporarily interrupted, the sending out to India of drafts of young soldiers shall have been resumed, there is reason to fear that sickness and mortality from enteric fever may again rise in proportion to the number and youth of the men so drafted. The history of enteric fever in the year under review only further confirms what the records of each succeeding year so clearly demonstrate: that "the relative liability to death from enteric fever was greatest in the age period 20-25, and in the first year of residence." But age and length of residence in India are not the only conditions which influence the prevalence of this disease. The history of enteric fever in Quetta during the two consecutive years 1898 and 1899 may be cited as an illustration of this. During the former of these years, in a European garrison of the average strength of 2,138, the admission rate from enteric fever was 108·3 per 1,000 of strength, and the death-rate 35·08. During the year under report, in a garrison of the average strength of 2,405, the admission rate from enteric fever was 10·8 per 1,000 of strength, and the death-rate 2·08. "This

great reduction at Quetta may fairly be considered, at least provisionally, as due to the detailed painstaking measures adopted in consequence of the outbreak in 1898, though it will be noticed the season of maximum prevalence was the same in both years. The number of fresh men arriving in drafts was much the same as in the preceding year." In this case at least the decrease could not be credited to the supply of susceptible materials having been shut off. A footnote added to the Report states that : "There has been an outbreak again in 1900," a somewhat disappointing sequence to the adoption of the measures which appeared to have had a decided effect in checking the progress of the disease. The Report again gives an excellent *résumé* of the latest additions to the literature of enteric fever. To this must be referred those who wish to know what is being done to extend our knowledge of the disease. The subject can be no more than touched upon here without unduly lengthening this *memorandum*. The general tendency of recent research is to show that the bacillus of enteric fever is widely disseminated throughout the organism of the individual who is the subject of it. "Any conception of the disease which regards it as merely affecting the alimentary canal only can no longer be maintained. On the contrary, so far from considering it an intestinal disease pure and simple, we should rather look upon it as a *modified form of septicæmia*." In all cases the bacillus passes into the blood, by means of which it is distributed to the most diverse organs. Outside the body its diffusion seems likewise to be wide. From a perusal of the abbreviated reports submitted by medical officers for 1899 may be gathered some idea of the variety of the suggested sources of enteric fever infection. The number of those who adhere to the "solely water-borne" theory of infection seems to be decreasing. The results of some of Hankin's examinations of the specimens of water sent to him for report seem somewhat remarkable. "The enteric microbe was detected in one out of four specimens of water that were stated to have been treated with permanganate and boiled." And :—"the results obtained in the year under review appear to confirm my opinion that the enteric microbe is one that flourishes better in comparatively pure than in very polluted water." The detection of the enteric fever microbe in water is far from easy ; experts, it may be remembered, failed to find it in the water supply of Maidstone during the prevalence of the recent great epidemic of enteric fever at that place, although there was a pretty general concensus of medical opinion that the disease had its origin in, and was disseminated by, the water.

10. The European Army of India suffered rather severely from *scarlet fever*. There were altogether 83 cases of the disease with six deaths. Indigenous scarlet fever is rare amongst the natives of India, and the different outbreaks of the disease amongst the troops appear to have been due in most part, if not altogether, to the importation of infection. The transport "Simla" was, perhaps, the source from which infection in all, or nearly all, the Indian cases of 1899 was derived.

11. There were 211 admissions, with 38 deaths, from *tubercle of the lungs*, as compared with 196 of the former and 37 of the latter in the previous year. The Sanitary Commissioner remarks that the annual reports for stations where tubercle occurred in greatest proportion throw no light on the subject.

12. *Pneumonia* was accountable for 340 admissions and 40 deaths, as compared with 190 of the former and 38 of the latter in 1898. As usual, the disease was most prevalent in the north-west of India, and in the cold weather. "The five men who died at Peshawar were all more or less debilitated by previous attacks of ague, and in each case the fatal illness developed after the man's participation in the fatigues of route-marching."

13. The unusual dryness of the year was probably connected with the decrease in the prevalence and fatality of *dysentery* and *diarrhœa*. Whilst the admission rate in the case of the former disease fell from 30 to 25, and the death-rate from ·78 to ·65, per 1,000 of strength, the admission rate in the case of diarrhœa fell from a ratio of 27 to 18, and there was no death due to it. Dysentery was most prevalent, as usual, in the Bengal Command, and in the Bengal-Orissa group.

14. From *abscess of the liver* there was a reduction in the number of deaths from 102 in the preceding year to 85 in the year under report ; but in addition to these 85, abscesses were also found in the liver after deaths attributed to several other causes. Of these additional cases in which *post-mortem* examination revealed the presence of hepatic abscess, the cause of death in 11 was returned as dysentery, and in five as enteric fever. The mortality from abscess of the liver was 32 times more frequent during the year among European than among Native soldiers.

15. The decrease in the admission rate from *venereal diseases* in the European Army of India during 1899 is a continuation of that which began in 1896. In 1895 the rate had attained a maximum of 522·3 per 1,000 of strength. From this it fell slightly in 1896 to 511·4 ; and in the following year, more considerably, to 485·7. In 1898 the decrease was marked, the rate falling to 362·9, or in a single year by 122·8. Decrease has been maintained in 1899, although at a less rapid rate than in the preceding year. In 1899 the recorded admission rate was 313·4, or less than the rate for 1898 by 49·5. In addition to the causes mentioned as probably conducing to reduction of the admission rate in the previous year, a list of others is given in the Report of the year under review. Of the latter, those which were perhaps most likely to have been attended with good results were measures which had for their object to lessen the opportunities for soldiers consorting with loose women by keeping the latter away, the effect of cantonment hospitals, constant examinations and surprise inspections of the men, presence of an energetic cantonment magistrate, and hospital stoppages. There were 14 deaths and 442 invalidings directly due to venereal disease against 17 of the former and 569 of the latter in the previous year.

16. The *Native Army* shared with the European Army in the improved health of the year. Its average strength was 128,529. The admission ratio which had fallen in the previous year from the decennial average of 917 per 1,000 of strength to 816 fell still further to 705, and the constantly sick ratio from 33 to 28 ; whilst the mortality ratio, exclusive of absent deaths, fell from 11·07 to 10·70. Ague was the chief cause of admission into hospital, and of itself accounted for 37 per cent.

total admissions; whilst the chief causes of death were pneumonia and remittent fever—monia having been accountable for 36 per cent. and remittent fever for 11 per cent. of the total aths. As usual, the Native soldier suffered far less than his European comrade from enteric fever d venereal disease, but more from influenza, cholera, dysentery, and respiratory diseases, especially eumonia.

17. The highest constantly sick rate in the Native Army was in Assam, the highest admission te in Bengal-Orissa, and the highest death-rate in the Hill Stations. Of the stations with garrisons a strength of not less than 1,000, Edwardesabad returned the highest death-rate of 28·04, a rate, owever, much below that of the previous year, when it was 40·61. Next follow Belgam and eshawar with death-rates of 22·85 and 18·55 respectively, both stations returning higher rates than 1898. It is stated in paragraph 41 of the Report that the principal cause of death in these stations as pneumonia, but, so far as Belgam is concerned, plague and not pneumonia would appear to have used the greater number of deaths; to the former 21, and to the latter only three deaths were due.

18. Instead of diminishing, in sequence to a year of high prevalence, in accordance with what its revious behaviour would have led one to anticipate, *influenza* increased in severity. The number f admissions due to it rose from 1,047 in the previous year to 1,586 in the year under review, and he deaths from four in the former to 13 in the latter.

19. From both *cholera* and *small-pox* the Native suffered more than the European Army. Of the former of these diseases there were 126 cases with 68 deaths, as compared with a single case in the European Army; whilst of the latter there were 46 cases with two deaths among the Native troops as compared with 14 cases and one death among the European troops. The Native garrison of Peshawar suffered most from small-pox; the disease prevailed in severe epidemic form in the city and district of Peshawar amongst the civil population.

20. *Ague*, although it caused nearly 37 per cent. of the sickness in the Native Army, was, probably owing to the dryness of the year, considerably less prevalent than in 1898. There was also a decrease in the admission rate from remittent fever, although an increase in the death-rate due to it. Remittent fever was of itself responsible for 147, or 11 per cent., of the total deaths in the Native Army.

21. As a cause of sickness and mortality enteric fever is of comparatively slight importance amongst the Native troops. Altogether, 18 cases with three deaths were registered under this head, out of an average strength of 128,529, as compared with 1,392 cases and 348 deaths in the European Army of an average strength of 67,697. The recorded death-rate in the Native Army was 0·02 per 1,000 of strength, and 5·14 in the European Army. In the previous year the number of cases of enteric fever recorded in the Native Army was greater, and the deaths 18 as compared with only three in the year under report. It should not be forgotten that in cases diagnosed to be enteric fever it is rare in the case of Native soldiers to have the accuracy of the diagnosis verified in the fatal cases by a *post-mortem* examination. "It may be worth mentioning," to quote from the Report, "that year by year one medical officer's diagnosis contributes a considerable proportion of the cases registered in the Native Army." The Principal of the Lahore Medical College is of opinion that "the occurrence of the disease has some connection with the dietary of the patients." He is inclined to the belief that as a native of India assimilates his diet to that of Europeans he becomes more liable to the disease.

22. The total number of deaths from *plague* in the Native Army was 45. There were 65 cases with 39 deaths in the Deccan group. The Sanitary Commissioner remarks that, as usual, the chief point brought out in the extracts from the reports of regimental medical officers is the benefit derived from quitting the infected lines and living in the open.

23. To *tubercle of the lungs* were attributed 440 admissions and 87 deaths. The Gurkhas are more subject to this disease than other Native soldiers. The six highest numbers of cases were all in Gurkha regiments. The remarks made by the Medical Officer of the 1st battalion of the 4th Gurkhas are significant. "The most crowded barracks usually furnish the greater number of tuberculous patients . . . . the effects of overcrowding becoming more noticeable in a year spent by the regiment entirely in cantonments." The conclusion arrived at by the Sanitary Commissioner with the Government of India is that, whether the Gurkhas are, or are not, more prone to tubercle than other Native soldiers, "it is quite certain that overcrowding and defective ventilation favour the occurrence of the disease. The Gurkhas are stationed in climates that produce temptation to exclude the cold fresh air from dwellings."

24. To *respiratory diseases* nearly 40 per cent of all the deaths in the Native Army were due. *Pneumonia* of itself accounted for 2,097 admissions and 480 deaths. Both the admission and death rates from this disease were highest, as usual, in the Indus Valley and the Hills. The Medical Officer of the 1st battalion 4th Gurkhas writes:—"As the infectious nature of the disease under favourable conditions is beyond dispute, it is not surprising to find that the barracks with least cubic space furnished the greatest number of cases, and that the cramped space available in the hospital wards likewise favoured the spread of the disease to other patients undergoing treatment for other diseases at the time . . . . It is hoped that before long the hospital accommodation will be brought up to the authorised scale."

25. As in the case of ague, the dryness of the year seems to have had the effect of reducing the prevalence of *dysentery* and *diarrhœa*. The admissions due to dysentery fell from a ratio, per *mille* of strength, in the preceding year, of 44·0 to 38·0, and the deaths from a ratio of ·49 to ·35; whilst the ratios of admissions and deaths from diarrhœa fell from 9·4 of the former to 7·1, and from ·20 of the latter to ·12.

26. There was a marked decrease in the prevalence of *venereal diseases* in the Native Army in the year under report as compared with 1898; the admission ratio falling from 40, per 1,000 of strength in that year to 34·1 in the year under review. The movement of the ratio upwards or downwards is confined within somewhat narrow limits from year to year. The lowest rate recorded was in 1877, the first year for which the figures are available: in that year it was 26·7. The highest rate was recorded in 1890, when it rose to 41·1. The Gurkhas suffered proportionately more than other Native troops. It is remarked that their post-coitional habits are said to be less cleanly." The circumstance, also, that they belong to a different race and country may have something to do with their being oftener the subjects of venereal disease in India than other Native soldiers, who are generally stationed in their own country and among their own people; in the same way that the alien British and Dutch soldiers suffer more from venereal disease in India and in Java than they do when stationed in their own countries in Europe. In the year under report, while Gurkha regiments had an admission rate of 75·7 from venereal disease, other Native troops had an admission rate of only 33·9 per 1,000 of strength.

27. The *jail* population was of nearly the same average strength as in the previous year, decreasing slightly to 110,016. The health of the prisoners still further improved, the death-rate falling, again, from 25·87 in 1898 to 23·87 in the year under report. Except from cholera and tubercle of the lungs, there was reduced mortality from all the principal diseases, but especially from "anæmia and debility." The three diseases, dysentery, pneumonia and tubercle of the lungs, which caused half the mortality in the preceding year, were again credited with 52 per cent. of the total deaths during the year under report. To dysentery, ordinarily the most fatal of jail diseases, 23 per cent. of the total deaths were due; to tubercle of the lungs 15 per cent.; and to pneumonia 14 per cent. The returns show a wide difference between the jail mortality recorded in the several administrations. In Assam, with a death-rate of 55·18, the mortality ratio was highest, followed at a considerable distance by the Andamans with a rate of 42·24. In none of the other jail administrations did the rate reach 30 per 1,000 of the jail population, whilst in four of them it was below 20. Berar and Madras, the former with a ratio of 13·32, and the latter of 16·13, recorded the lowest death-rates. Of the two principal diseases, cholera and tubercle of the lungs, from which some increase of mortality occurred during the year, as compared with 1898, the former was entirely absent from the jails of the Punjab, Berar and the Andamans; it was only in the jails of Assam that cholera prevailed with great severity. In the latter province the mortality due to it reached a ratio of 13·61 per 1,000 of strength of the prison population; in one other province only, Burma, was it as high as one per 1,000. From remittent fever Madras alone records no death; whilst the province of Assam records, as in the case of cholera, the highest death ratio from this disease also. The jails of all the administrations suffered to varying degrees from dysentery; the Andamans recording a death-rate from this cause of 15·58, and Bengal and Assam 6·18 and 6·05 respectively. The jails of Berar and of the Punjab were remarkably free from this scourge of prison populations, the former returning a death-rate due to it of only 1·40 and the latter of 1·59 per 1,000 prisoners. The degree to which bowel complaints prevail in a jail may usually be taken as a fair indication of its general hygienic condition. The mortality from respiratory diseases was least in the jails of Madras and Burma, and highest in Assam and the Punjab; in the two former it was under two, and in the two latter it was about six per 1,000. Tubercle of the lungs caused the highest mortality in the Andamans and the lowest in Berar. As bearing upon the question of the comparative immunity of natives from enteric fever, it is to be noted that out of 40,792 cases of "fever" admitted into all Indian jails, only 21, with 12 deaths, were returned as enteric fever. Of small-pox deaths there were only five; and of cholera only 54. The Sanitary Commissioner truly remarks:—"When it is considered that the average daily strength of prisoners in India was 110,016 the fewness of the cases of cholera and small-pox is a remarkable tribute to the medical management of these institutions." During a year when plague was so widespread and fatal, there were only five attacks with two deaths recorded in the jails of India.

28. The rest of the subjects of the Report have already been separately dealt with in our *memoranda* on the several provincial sanitary reports, and need no further notice here. The Report before us is less bulky than its predecessor and is a model of conciseness, clearness and accuracy.

29. *Summary.*—The year was one of short and irregularly distributed rainfall. Whilst in places, especially on the eastern side of India, the fall was in excess, in Western India it was greatly in defect. To the dryness of the year was due, it is believed, the diminished prevalence of malarial diseases, which was a marked feature of its medical history. The European Army, of an average strength of 67,697, was healthier than in the preceding year; the ratios of admission into hospital, of constantly sick, of deaths, and of invaliding being all lower. The chief causes of admission were, again, venereal diseases and ague; whilst the chief causes of death were, also again, enteric fever and hepatic abscess. The chief causes of invaliding, as of admissions and total sickness, were venereal diseases and ague. Of the four Commands, Madras again records the lowest mortality rate, but the highest constantly sick and admission rates. The Punjab again records the highest mortality rate, although this has fallen to nearly half of what it was in the previous year. All of the Commands were healthier than in 1898. The larger stations, with garrisons of 1,000 or upwards, which returned the highest death-rates were Peshawar, Lucknow, Umballa and Bangalore. All of these, except the last, returned highest rates in the previous year. From three of the chief diseases, cholera, small pox and influenza, only a single death was caused by each. The occurrence of only one case of cholera in the European Army of India is without precedent in the records of any previous year. Ague and remittent fever were both less prevalent than in 1898, the consequence in part, no doubt of the exceptional dryness of the year. Enteric fever was much less fatal than in the previous year the number of deaths due to it falling from 654 to 348. This welcome decrease was probably due chiefly to the influx of drafts of young soldiers from England having been less in 1899 than in the preceding year. Several deaths from scarlet fever were recorded. Infection was traced with more or less of certainty in most, or all, of the outbreaks to the transport which conveyed the troops to India. Tubercle of the lungs and pneumonia caused almost the same number of deaths as in 1898;

e sickness and mortality from bowel-complaints showed a marked decrease. There was at e same time a decrease in the number of deaths from liver abscess. The continued decrease in the evalence of venereal diseases in the European Army is a gratifying feature of the year's returns. om a maximum of 522·3 per 1,000 in 1895, the admission rate has fallen to 313·4 in the year under port, a practical proof of the success of the sanitary measures recently enforced with the object of eventing the spread of these diseases amongst our young soldiers in India.. The Native Army ared in the improved health enjoyed by the European troops. The chief cause of admission into spital in the Native Army was ague, and the chief causes of mortality pneumonia and remittent ver. The Native Army, as usual, suffered comparatively little from those scourges of the European rmy, enteric fever and venereal disease. Cholera and small-pox were more prevalent than amongst e European troops. Respiratory diseases were the chief cause of mortality, pneumonia alone account-g for 480 deaths. The diminution in the prevalence of venereal diseases noted in the case of the uropean Army extended to the Native troops. The health of the jails of India, which had shown mprovement in the previous year, still further improved. Except from cholera and tubercle of the ngs, the mortality among the prisoners from all of the principal diseases was less.

14th May, 1901.

No. 2.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Bengal for 1899.

The rainfall recorded for the year exceeded that of the previous year by five inches, and was nearly ten inches more than the normal mean. It is stated that, although above the average in most places, it was not seasonable, The irregular distribution of the rainfall had an unfavourable effect on the agricultural cutturn; whilst its deficiency in September, and the absence of rain floods in October, "probably accounts," the Sanitary Commissioner thinks, "for the great unhealthiness of this province during the last quarter of the year." The principal food grains were cheaper than in the previous year, and also cheaper than the average. The high prices which had prevailed in 1897 gave place to low prices, and a return to prosperous times in 1898, followed by even lower prices in the year under report. As measured by the death-rate, the year was not so healthy as its predecessor. This result was unquestionably in great part due to the high birth-rate of the year under report, as compared with the birth-rate of the previous year. But, apart from the influence of this cause in raising the death-rate, an examination of the mortality returns of infants under one year of age for the two years shows that, whilst in the previous year the deaths amongst these were in the ratio of 192·35 per thousand, they were in the ratio of 246·13 in the year under report. There is, perhaps, no more sensitive gauge of the public health than the ratio of mortality amongst the infant population. The unusually large accession to the population of the province, which a birth-rate of 42·96, as compared with 35·79 in the previous year indicates, and the rise in the death-rate recorded for the infant population from 192·35 to 246·13, would together largely account for the higher death-rate of the year under report, as compared with that for 1898. The tendency which, under ordinary conditions, the death-rate has to rise and fall with the birth-rate is well illustrated by the figures for the two years 1898 and 1899. In the former the recorded birth-rate was 35·79 per thousand of population, and the death-rate 26·57; in the latter the birth-rate was 42·96 and the death-rate was 31·21. The proportion which the birth-rate bears to the death-rate of each of these two years is thus seen to be nearly the same. Besides the exceptionally high birth-rate of the year, another cause which must have contributed to raise the death-rate is that noted in the Government review of the Report. The natural increase of the population since last census was taken has been considerable. It is represented by the excess of births over deaths for the period 1892–99, and amounts on the average to 4·21 per thousand of population for each of those years, or the difference between the average birth-rate of 35·62, and the average death-rate of 31·34. We have thus for the year under report a birth-rate obtained by calculating the numbers of births resulting from a larger population on the figures of a smaller population. Obviously, the outcome of such a procedure would be to raise the recorded above the real birth-rate.

2. The Sanitary Commissioner is, no doubt, correct in attributing the high *birth-rate* of the year mainly "to the exceptional healthiness of the year 1898, and the greater prosperity of the people, resulting from two years of good harvests in succession, during 1897 and 1898, which enabled them thoroughly to recover their vitality after the preceding years of scarcity." The birth-rate is the highest hitherto recorded for the Province, but is exceeded by that of the Punjab, the North-Western Provinces and Oudh, and the Central Provinces. That the real birth-rate is still higher than that recorded is shown by the investigations made by the Inspectors and Sub-Inspectors of vaccination. These officers found that of the births and deaths regarding which they made inquiry in the towns and villages, 1·13 of the former, and 1·14 of the latter, had not been reported at the Police Stations by the *Chaukidars* or Watchmen. That the discrepancies between the reported numbers of births and deaths, and those ascertained by special inquiry, should be so inconsiderable, is proof of the remarkable improvement accomplished in the registration of vital statistics in the Province of Bengal within the last few years. Taking the figures as they stand to represent with approximate accuracy the number of births and the number of deaths, the natural increase of the population in the single year under report has been no less than 834,935. In other words, the births exceeded the deaths by this number.

3. Accompanying, and without doubt, partly at least, owing to the high birth-rate, there was a high death-rate. This latter rose from 26·57 per thousand of population in the preceding year to 31·21 in the year under review, and was higher than the rate recorded for the past ten years by 1·93. This increased mortality, the Sanitary Commissioner writes, "was chiefly due to the unhealthiness

of the year, as testified to by the Civil Surgeons of 33 out of 45 districts, the mortality fr[illegible] and cholera having risen from 19·97 and ·91 in 1898 to 22·61 and 1·51 respectively." The addition the population of a much greater number than in the previous year of the class yielding the high death-rate, that is to say, of infants, could not fail to contribute to a higher death-rate in the y under report. At the same time the increase in the mortality amongst infants from 192·35 in t previous year, to 246·13 per thousand in the year under report, shows that when the health of the t years is measured by the comparative mortality recorded for the same section of the populati 1889 was less healthy than its predecessor. As with the birth-rate so with the death-rate, and for t same reason the growth of population since last census must have tended to raise the recorded abo the real death-rate. In the table included in paragraph 18 of the Report, giving a list of are recording excessive mortality due to cholera and fever, it is interesting to note the birth-rates in t areas recording the highest death-rates. It will be seen that, as the Sanitary Commissioner remarks, t first five places in the list are occupied by five of the rural areas in the Murshadabad district. Takin this district as a whole, it records a death-rate of 43·00 per thousand of population against the pr vincial rate of 31·21. At the same time, it records a birth-rate of 48·68 against the provincial rate 42·96. Of the five rural areas of the district with the highest death-rates, two record birth-rates upwards of 48, and two of upwards of 52 per thousand of population. The high birth-rates and th high death-rates would thus appear to be intimately related to each other. The greater the proportiona number of those least capable of resisting the tendency to death, that is to say, of infants, in th population, the higher ordinarily will be the death-rate in that population. "As usual," writes the Sanitary Commissioner, "the mortality from cholera, dysentery, and diarrhœa, and other causes, was much higher in towns than in rural areas, while fever was more prevalent in rural areas." The cause of this difference was attributed in the previous year's report to "overcrowding in towns with its attendant evils, and to absence of proper drainage and good drinking water in rural areas." In our Memorandum on the Report for 1898, we suggested as an alternative explanation the more intelligent differentiation of the causes of death in towns as compared with rural areas. If the table given in paragraph 19 of the Report be examined, it will be found that whilst towns record a ratio of 17·08 deaths from fever, rural areas record one of 22·89. On the other hand, whilst towns record a ratio of 10·11 deaths, under the heading of "other causes," rural areas record a ratio of only 5·59 under that heading. These figures would certainly seem to indicate higher fever mortality in rural areas than in towns; but if the deaths recorded as due to fever are added to those recorded as due to "other causes," in the case of towns and rural areas, the totals will be found closely to approximate. In towns the death-rate from fever and "other causes" combined was 27·19; and in rural areas 28·48. The inference may be suggested that whilst "fever" is made to include indiscriminately a variety of diseases amongst the more ignorant rural population, these diseases have been somewhat more successfully differentiated in towns, the inhabitants of which may be assumed to be more intelligent. The statistics of mortality recorded by qualified medical practitioners in the North-Western Provinces clearly show that a considerable proportion of the deaths caused by diarrhœa and dysentery are ordinarily credited to fever. The recorded ratio of only ·45 deaths per thousand of population in the rural areas of Bengal certainly falls far short of the actual ratio. The higher ratio of 3·07 deaths attributed to these diseases in towns may be due, as already suggested, to a somewhat more intelligent differentiation of diseases rather than to the comparatively greater prevalence of bowel complaints in towns than in the country. It is hardly credible that the inhabitants of towns are six or seven times more liable to die from these diseases than the inhabitants of country villages. With a view to ascertaining, with some near approach to accuracy, the proportion of deaths caused by each of the chief diseases, the experiment carried out in the North-Western Provinces might, perhaps, be usefully carried out in Bengal. In the North-Western Provinces returns of all the deaths, the causes of which have been verified by qualified medical men, are yearly submitted to the Sanitary Commissioner, and the results tabulated by him in his Annual Report. A comparison made between these and the results obtained from the returns made up from the reports of the *Chaukidars*, who are the chief agents employed in collecting the provincial statistics, helps to guard against fallacious conclusions being drawn from the latter, and to show in respect of what diseases they are most likely to be deceptive.

4. *History of Chief Diseases.—Cholera*, from which India had enjoyed remarkable immunity during the previous year, caused 107,678 deaths, as compared with 65,020 in 1898. Although not exceptionally destructive of life during the year under report, it was widespread, no district of the 46 having being entirely exempt from it. The Malda district suffered excessively, recording a cholera death-rate of no less than 6·28 per thousand of its population against only ·12 in the previous year. As usual, some endeavour is made to explain the outbreak and progress of the disease. The Civil Surgeon of Malda writes:—"After the terrible cyclone that blew over over Bhagalpore in October, several dead bodies and carcasses came floating down the Ganges, and were left in the *churs* all along the western border of the district. The epidemic dates from that very month. There was raging just then a terrible epidemic on the other side of the Ganges too." The latter statement would suggest the explanation that the outbreak was simply an extension of the disease across the river, which does not prevent constant intercourse between the inhabitants of its two banks. The Civil Surgeon of Puri gives a graphic account of the circumstances attending the prevalence of cholera in his district, which, next to Malda, suffered more than any other in the province. Those circumstances are now everywhere acknowledged to be actively concerned, if not in originating the disease, at all events in intensifying and spreading it. He says:—"We have, therefore, all the elements necessary to manufacture a cholera epidemic, viz., poor physique to start with (Hindu widows), privation of all sorts, starvation, indigestible food, polluted water, exposure to rain, wind and sun, overcrowding on the journey, with no doubt insufficient opportunities for obeying the calls of nature (and when they do relieve themselves it is generally at the edge of their drinking-water supply!)." To those not conversant with pilgrimages in India, the prevention of the conditions conducing to the "manufacture" of a cholera epidemic, thus graphically described by Dr. Hendley, may seem comparatively easy. In reality it is very much otherwise. In some of the other districts in which the disease prevailed in severe epidemic form, "the early cessation of the rains and the consequent earlier pollution

water supply" are assigned as the chief factors concerned in the development of the epidemics. Anti-cholera inoculation would not appear to be making much progress. On this subject the Sanitary Commissioner writes :—"From isolated returns like these no inference can be drawn regarding the prophylactic quality of inoculation, as well as the period for which immunity is conferred by a single inoculation." He adds that the information now received relating to the protection afforded to the inoculated coolies while *en route* to the labour districts is meagre. Such information with regard to the coolies annually despatched to Assam has long been awaited.

5. *Small-pox* was somewhat less fatal than in the previous year. The death-rate due to it was ·18 per *mille* of population as compared with ·20 in 1898, and with ·20 the average of the past 10 years. Over two-thirds of the total deaths from it were returned by Orissa alone. In Cuttack, a district of the Orissa division, in which the disease was very prevalent, the cause of the heavy mortality is attributed by the Civil Surgeon to insufficient vaccination, and to the practice of inoculation. Vaccination recovered some part of the ground lost during the previous year; but the total number vaccinated still fell short of the figures recorded for 1897–98. In the latter year 2,319,536 operations were performed, as against 2,225,252 in the year under report; and yet during the latter the number of operators employed was greater by 114 than in the previous year. Under these circumstances the amount of work done might have been expected to be greater; but after reading the account given by the Sanitary Commissioner of the way in which his deputies were mainly employed during the year, the wonder is that the results of the season's operations were so satisfactory as they are recorded to have been. Major Dyson describes the duties which occupied his three Deputies during 1899 in the following words :—"Captain Clemesha was almost entirely engaged in plague work, and Captain Rogers in inspecting the sanitary condition of the riparian municipalities north of Calcutta, while Captain Hayward's time was occupied in superintending plague measures in and around Patna. These officers were consequently unable to inspect vaccination work." It may be a question whether, in the absence of the supervision of the Deputy Sanitary Commissioners, the returns of vaccination can be accepted with the same confidence as usual. It is common experience that nowhere in India can the strictest supervision of vaccination be relaxed without risk of falsification of returns following. It is unfortunate that, owing to the exigencies of the public service, officers appointed to supervise vaccination as part of their duties had to be withdrawn for employments which left them no time to make personal inquiry into the work of vaccination. Like his Deputies, the Sanitary Commissioner himself found his time so fully taken up with plague duties that he must have been practically unable to give any part of it to the inspection of vaccination. In the Government review of the Sanitary Commissioner's Report it is stated :—"Major Dyson was on tour for 160 days during the year. Practically, the whole of this time was taken up with the organisation and inspection of Plague Camps." In the Western Circle, Assistant Surgeon Gopal Chandra Mukerji inspected 12,592 operations, and the Civil Surgeons are stated to have shown greater activity in the work of inspection than in the previous year. The percentage of successful cases recorded in primary vaccination was 97·67, or almost the same as in the previous year. In re-vaccinations the number of operations decreased from 60,167 to 48,537, and the percentage of success from 67·34 to 49·59. This decrease in the percentage of success is not, perhaps, to be regretted; it may imply a more rigorous exclusion of unsuccessful or doubtful cases from the list of those hitherto entered as "successful." A satisfactory feature of the season's work is the more general use of vaccine-lymph direct from the calf. The total number of primary vaccinations performed direct from the calf during the year shows an increase of 35,000 operations as compared with the previous year. It is satisfactory, also, to find that there has been a substantial increase in the number of children under one year of age who were submitted to be operated upon. This number rose from 502,300 in the previous year to 619,068 in the year under report.

6. The recorded mortality from *fever* was greater than in the previous year. But here again the figures are apt to be deceptive. In the first place, registration of vital statistics has vastly improved since 1892, and fewer deaths from fever, as from other diseases, remain unrecorded. And in the second place, the population of the Province has much increased since last census was taken, whilst the census figures are still used in calculating percentage of births and deaths. Still, when every allowance is made for these causes, as well as for the record under the head of fever of many deaths due to other causes, it remains true that, in the words of the Sanitary Commissioner, this disease "exercises a terrible influence on the health and prosperity of the people." During the year under report, nearly 73 per cent. of the total deaths from all causes were recorded under the head of fever. In the Government Review of the Sanitary Report, reference is made to a special report by Captain Rogers on the fever prevailing in the riparian municipalities on the eastern bank of the Hooghly. The report is described as a "a particularly well reasoned and valuable document." Some of the inquiries made by Dr. Rogers are briefly described. "The remarkable feature of the report is the very great effect which the provision of a filtered water-supply is shown to have in reducing the fever rate in areas which contain every other known factor, including the anopheles mosquito, productive of a high rate of malaria." The cause, or causes, of fever and of its cyclical recurrence over wide areas in an intensified and destructive form have never hitherto received an explanation which can be regarded as complete. Perhaps it may be found possible to include Captain Rogers' report, or a review of it, in the Sanitary Commissioner's Report for 1900.

7. The mortality from *dysentery* and *diarrhœa* increased over that recorded in the previous year in approximately the same proportion as did the mortality from fever. The number of deaths from these two diseases rose from 37,155 in 1898 to 41,334 in the year under report, at the same time that the deaths from fever rose from 1,419,483 in the former year to 1,607,279 in the latter. The Sanitary Commissioner thinks the increased prevalence of bowel complaints "was to some extent due to the causes which led to increased cholera in many districts, viz., early cessation of the rains and the early pollution of the water-supply." It would perhaps be safer to say that increased cholera in many districts coincided with early cessation of the rains and the early pollution of the water-supply; at all events, until these conditions and the increase of cholera can be definitely proved to have stood

towards each other in the position of cause and effect. Reasons have already been given for accepting without reservation the accuracy of the returns which show bowel complaints to have been from six to seven times more fatal in towns than in rural areas.

8. Regarding *plague*, there is little told that can be said to be new. The observation camps at Chausa, Chakradharpur and Mairwa, situated on the western border of the Province, "were in full working order throughout 1899." The Sanitary Commissioner says they successfully intercepted "almost all" the suspected cases of plague trying to pass into or out of the Province. In the Government review of the Report, the work done at these camps is thus summed up :—"At the camps which were in existence at the close of the year, a total of no less than 1,797,350 persons were examined, of whom 15,651 were detained as presenting suspicious symptoms. Twenty-nine deaths occurred among the detenus, of which eight were due to plague.

9. *Sanitary Works.*—Expenditure appears to have been devoted to the maintenance and improvement of existing sanitary works rather than to the initiation of new ones. This year, again, the precautionary measures adopted with the object of preventing the spread of plague absorbed large sums which might otherwise have been spent on sanitary works of a permanent character. The most important sanitary improvement effected during the year was the completion of the new water-works at Berhampore. The Sanitary Board met three times during the year. Preliminary estimates were prepared under the orders of the Board for improvement of the Darjeeling water-supply and for the Patna waterworks, and various estimates and plans of sanitary works were submitted to the Board for an expression of opinion. It appears that the position and functions of the Sanitary Board in Bengal are different from those fufilled by other Sanitary Boards in India, inasmuch as it has been, and still remains, in practice mainly a consultative body. The Board agree that Mr. Buckley's note in their proceedings of the 10th June, 1899, in which he wrote, "What I fear and what I feel is that in Bengal the Sanitary Board is of little practical good, and that somehow or other it is not in the least what the Secretary of State, the Government of India, and the Government of Bengal intended that it should be," is correct. If after 10 years' experience the Board still finds itself of "little practical good," it might perhaps be time to confer upon it the "definite executive authority" which it seems to deem needful to render it more useful.

10. *Summary.*—The year, although, as measured by its death-rate, less healthy than its predecessor, cannot be described as having been unhealthy, at all events until near its end. The normal rainfall was exceeded ; and food grains were cheaper than ordinary. Following an exceptionally healthy and prosperous year, 1899 returned the highest birth-rate hitherto recorded for the Bengal Province. Accompanying, and in part at least owing to this high birth-rate, there was a high death-rate. Improvement of registration of vital statistics, and increase of population since last census was taken, helped to raise the recorded above the actual birth and death rates. Cholera was more fatal than in 1898, but although widespread, the mortality due to it was not excessive except in a few districts. The death-rate from small-pox was only 0·18 per thousand of population. Vaccination recovered much of the ground which it had lost in the previous year, but the numbers vaccinated were still below those for 1897–98. Unfortunately, owing to other duties mainly connected with plague, neither the Sanitary Commissioner nor his Deputies were able to devote personal attention to the inspection of vaccination. Fever was credited with having caused no less than 73 per cent. of the total mortality of the year. Fatal as fever itself always is, a large proportion of the deaths attributed to it are unquestionably due to other diseases. Bowel complaints were more fatal than in 1898, and it is certain that they were more fatal than the returns would show them to have been. The Sanitary Board held three meetings during the year. The positions and functions of the Board in Bengal are different from those of Sanitary Boards in other Provinces of India. Its members are of opinion that the Board will continue to be wanting in practical usefulness until it has been endowed with some measure of executive authority. Expenditure on sanitary works during the year was devoted to the maintenance and improvement of existing works rather than to the initiation of new ones.

14th May, 1901.

No. 3.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of the North-Western Provinces and Oudh for 1899.

The preparation of the report fell to the Officiating Sanitary Commissioner, Major Giles, I.M.S., who was in charge of the Department during no part of the year. The weather was characterised by several important departures from normal. There was a general failure of the winter rains. During the first three months of the year practically no rain fell, except in a few stations in or near the hills, and the last two months were absolutely rainless. On the other hand, the ordinarily dry months of April and May recorded more than the usual amount of rain. The monsoon set in, as usual, about the middle of June, and continued to be, on the whole, satisfactory up to the middle of August ; but from this time the rains may be said to have entirely ceased, September having been in most districts rainless, with the exception of a couple of days about the middle of the month. The temperature of the year did not vary greatly from normal. As might have been expected, the unusual rainfall in April and May tended to lower the temperature of those two months, whilst as a consequence of the premature cessation of the monsoon, temperatures during the closing months of the year were higher than usual. There was only a fractional difference in the mean price of food grains during the two consecutive years 1898 and 1899.

most remarkable feature of the year was its *birth-rate* of 48·09 per 1,000 of population, the ...est hitherto recorded. The rate for the previous year was 37·35, and the mean for the previous ... years 35·69. The high birth-rates which characterised each month of the year under review ...ere a continuation of those which began to be recorded during the latter half of the preceding year, ...d were due, doubtless, to the same cause, the cessation of a prolonged period of high prices of food ...erywhere and of scarcity or famine over wide areas, succeeded by a return of prosperity and the ...pid recovery of the population from the effects of hardship and distress. The number of births ...ceeded the number of deaths by 761,731. An addition in a single year of upwards of three-...arters of a million, or 15·97 per 1,000, to the population of a province already densely inhabited ...er a large part of its area, is doubtless a remarkable proof of recuperative power from the effects of ...vere and prolonged distress; but it is apt to suggest certain anxieties for the future, in the case of ...people chiefly dependent for subsistence on the cultivation of a soil liable to periodical and ...tensive failure of its crops. During the past 19 years the population of these provinces has ...creased by more than four and a quarter millions. During the same period, the common food ...ains have risen in price from a mean of 21·53 *seers* per rupee in the first 10 of those years, to 16·90 ...n the last of them. Unless wages have increased proportionately with the increase in the price of ...he staple food grains of the people, the struggle for existence must have been growing more acute. The growth of population during these 19 years may stand in no casual relation to the rise in the price of food; the rise may have been due to other causes, but increase of the population numbers and of the food prices mentioned appear from the returns to have been going on together. Although, during the year under review, all of the districts return unusually high birth-rates, the Sanitary Commissioner shows that the increase was most marked in the districts famine-stricken in 1897. This, he says, "would appear to justify Doubleday's well-known generalisation, that one of the consequences of famine is to increase fertility."

3. Accompanying the increase in the birth-rate, the *death-rate* rose from 27·38 per 1,000 of population in the previous year to 33·19 in the year under review. This large increase was, in part at least, due to the still larger increase in the birth-rate of the year. Not only was a far greater addition made to the population of that section of it most liable to death, that is to say, of infants, but the rate of mortality was higher amongst those under one year of age than it was among those of the same class and age in the preceding year. Whilst in 1898 the number of children born was 1,751,725, and whilst those died at the rate of 224·0 per 1,000 living, in the year under report the number of children born was 2,255,627 and these died at the rate of 323·1 per 1,000 living. Put otherwise, children under one year of age contributed 359,621 to the total number of deaths in the previous year, children under one year of age contributed 530,355 to the total number of deaths in the year under review. In paragraph 10 of his Report the Sanitary Commissioner gives the names of the six districts which returned the highest death-rates during the year. Excluding from these Naini Tal, the circumstances of which are exceptional, owing to the constitution and annual movement of its population, the remaining five districts return death-rates of from 39·07, the lowest, to 41·93, the highest. Turning to the tables recording the birth-rates, it will be seen that every one of the five districts returns a rate above the provincial average, Lucknow recording the lowest of 48·37 and Etah the highest of 61·14 per 1,000 of population. If the high death-rates of these districts were due solely to their exceptional unhealthiness, one would expect as a result of the enfeeblement of the people from such unhealthiness to find low birth-rates recorded. But the birth-rates are, on the contrary, high; and from this it seems fair to infer that a high death-rate does not necessarily imply unhealthiness of a population, but may sometimes be due, in part at least, to a birth-rate so high as to be of itself an indication not of unhealthiness but of its opposite. In paragraph 19 of the Report it is stated that "the infantile death-rate in 1899 was 264·7." It is not clear how these figures were arrived at. In a preceding table the population numbers of children under one year of age, according to last census, is given as 1,640,597, and the deaths among them as 530,355. Those figures yield a ratio, not of 264·7 but of 323·2; and these latter figures are in agreement with those given in Annual Form No. IV. page 8B of the Appendix. It would, perhaps, be preferable to calculate the infantile death-rate by using, not the census number of children under one year of age, but the number of children born during the year for which the calculation is made. If the latter method of making the calculation is adopted, the infantile death-rate for the year will work out to be 230·51 per 1,000 of children born, instead of 323·2.

4. This year again, the Report contains a very useful return embodying the results of the verification of deaths by medical officers, medical subordinates, and medical practitioners generally. These results provide a sort of standard by which to gauge the general returns of death causes recorded by the unprofessional agents employed to collect and record the vital statistics of the province. The total number of deaths, the causes of which were verified by qualified medical agents during the year, was 9,684. Of this number 4,484 were of children under 15 years of age, 3,011 of adults from 16 to 45 years of age, and 2,189 were 46 years of age and upwards. The number of deaths attributed to fevers of all kinds holds the foremost place, as in the provincial returns; but instead of accounting for approximately four-fifths of the total number of deaths from all causes during the year, as in the provincial returns, they form less than one-third of the total. Of the 3,059 deaths diagnosed as due to fevers of all kinds, the specific form of fever is not stated in 1,943 of the cases. Of the fevers specified, seven fatal cases are classed as enteric. In connection with the question of the supposed prevalence of enteric fever amongst native children, sometimes adduced to account for the remarkable immunity which adult natives appear to enjoy from this disease, it may be noted that there was no death recorded as due to enteric fever among children of less than eight years of age. Of the seven fatal cases of enteric fever diagnosed, four occurred amongst persons between the ages of eight and 15 years, and three amongst those between 15 and 45 years. As causes of death, dysentery and diarrhœa would appear to play a far more prominent part than they have assigned to them in the provincial returns. No fewer than 1,439, or more than one in seven of the total 9,684 deaths from verified causes, were due to these diseases. In the provincial returns only 27,206 out of a total of 1,556,821, or about one in 57, are attributed to these diseases.

5. *History of Chief Diseases.*—The number of deaths attributed to *cholera* was 8,142, the [illegible] recorded from this disease for any of the last 29 years, with the single exception of 1898. There have thus been two consecutive years of exceptionally low cholera mortality. But for the fact that its incidence was unusually light, the history of the disease appears to present no special feature during the year. As in most years, the mortality was highest in August: and, as also in most years, the first three months were those of least cholera prevalence. In the Report by Captain Fullerton, Deputy Sanitary Commissioner of the First Circle, an interesting account is given of the outbreak of cholera in the Dehra Dun district, and of the remarkable effect the closing of the canal which ran through the station had in cutting it short. "The closing of the canal was followed by the complete subsidence of the disease in less than a week." In a sample of water taken from this canal and sent to Mr. Hankin for examination "the microbe of cholera was discovered in a virulent form." Captain Fullerton has much confidence in the efficacy of the permanganate of potassium disinfection of wells during cholera outbreaks, and gives it as his opinion that if the disinfection "is properly carried out the disease will disappear in from three to seven days."

6. Like cholera, *small-pox* has been in remarkable abeyance during the two years 1898 and 1899. In the former of these years the death-rate from this disease was only 0·05 per 1,000 of population, and in the latter 0·04. Excepting in 1895, when it was the same, the rate for the year under report is the lowest on record in these Provinces. The work of the Vaccination Department has been satisfactory. The total number of primary vaccinations increased from 1,227,261 in the previous year, to 1,365,931 in the year under report. Part of this increase is accounted for by the increased strength of the vaccination staff as compared with its strength in 1898-99. But apart from this, the returns show that, on the average, each vaccinator performed 1,683·11 operations, as compared with 1,598·50 in the previous year. Yet, although the total numbers vaccinated compare favourably with the numbers for 1898-99, they show no great increase over the number of primary vaccinations in 1895-96 and in 1896-97. But in the year under report there was a very marked improvement in the percentage of successful primary operations in which the result was ascertained. This percentage increased from 94·96 in the previous year to 97·00 in the year under report. Humanised lymph is still mostly used in these Provinces; but one large bovine depôt is established at Lucknow, and minor depôts at Allahabad and Bahraich. The crude lymph as supplied from these depôts is said not to retain its efficacy for any length of time. Perhaps it might be expedient to select and send an officer of the Department to Shillong to study the process of animal lymph preservation practised there by Colonel Campbell, the Civil Surgeon. This process is stated to have proved completely successful. Perhaps the most satisfactory feature of the season's work is the large increase in the amount of infant vaccination. The number of infants successfully vaccinated increased from 633,534 in the previous year to 848,675 in the year under review. The Second Circle, which includes the Province of Oudh, has hitherto shown a disappointingly small return of infants vaccinated; but in the year under report the number has increased to 317,575 from 199,199 in the preceding year. Than this there could be no better proof that the prejudice against vaccination, still strong in many parts of the Province of Oudh, is being gradually overcome.

7. The number of deaths registered under the head of *fever* increased from 1,063,596 in the preceding year to 1,245,260; but, as the Sanitary Commissioner remarks, "the heading of fever has so loose an application in our available statistics that it can hardly be said to have more than a rough proportionate relation to the general amount of malarial disease." The researches of Laveran, Ross, and others, whilst they shed a flood of light on much that hitherto has been obscure regarding so-called malarial fevers, show that experience in the past had discovered in drainage one of the most effectual means of diminishing or extinguishing those fevers in localities in which they were endemic. Drainage will, apparently, lose none of its importance in consequence of the discovery that certain species of mosquitoes are active agents in the dissemination of malarious fever; since by depriving the mosquitoes of the medium in which they breed, it will tend to bring about their diminution or extinction. Nor, when prevention has failed and the disease has been contracted, is it probable that quinine will cease to retain its position as one of the most efficient remedies in the treatment of malarial fever. Indeed, judging from the system of treatment recommended by Ross, the probability is that, instead of losing, it will in the future gain in importance as a remedy.

8. Only 27,206 deaths from *dysentery* and *diarrhœa* were registered during 1899. Reasons have already been given for the belief that the mortality from these diseases is higher than the returns would lead one to conclude. The urban death-rate ascribed to them was 2·08 per 1,000 of population, as compared with 0·47 in rural areas. It is difficult to believe that the inhabitants of towns are nearly five times more liable to die from these diseases than the inhabitants of country villages.

9. It would have been satisfactory to have had some explanation of the sudden increase in the number of deaths registered under the head of "all other causes." From 167,481 in the previous year these have risen to 250,644 in the year under report. An examination of the returns of deaths at pp. 12B.-17B. of the Appendix rather tends to weaken confidence in even some general approach to a correct record of deaths according to their causes having been reached. For example, in the Etah district, out of a total death-rate of 41·88 from all causes, 10·21 are credited to "all other causes"; the next district on the list, Muttra, records a death-rate of 37·67 from all causes, and 0·50 from "all other causes." Similar contrasts will be found in the returns for towns. Farukhabad and Agra record almost the same death-rates from all causes, that of the former town being 41·05, and of the latter 41·14; yet the death-rate from "all other causes" in Farukhabad was 1·85, and in Agra 20·78.

10. Until nearly the end of the year no indigenous case of *plague* was reported in these Provinces. There were a few imported cases of the disease, but these gave rise to no others. Towards the end of November, however, a family of three persons of the weaver class, returning from Bombay to their homes in a village of the Allahabad district, appear to have brought plague with them and to have communicated it to other inhabitants of the village. Cases continued to occur until the end of the

der review, but the measures taken to prevent its spread beyond the village seem to have been successful. The account of this localised outbreak belongs to next year's report. The Sanitary Commissioner gives a list of officers, 80 in number, employed at one time or another on plague duty during 1899. He writes :—"Inspections at border stations have been steadily maintained throughout the year. As a matter of fact no case of plague has, however, been detected at any border station, while, on the other hand, the less elaborate inspections at minor stations have from time to time detected several cases of real or suspicious plague (two in the year under review)." The total number of cases brought to light is, however, very small in proportion to the large agency employed."

11. *Sanitary Works.*—Of the 104 municipalities in these Provinces only nine have as yet been provided with waterworks; but these nine towns together contain approximately 1,038,433 inhabitants, or nearly one-third of the total population of all the 104 municipalities. Much attention was given during the year to measures designed to maintain the water supplied by these works of a high standard of purity. Further precautions were deemed needful to protect the Jumna from contamination near and above the intake of the Agra water supply. The filtering area of the Agra waterworks being considered to be insufficient, it was decided to increase it by the addition of another filter bed. Excepting of that delivered by the waterworks at Agra, the quality of the water supplied to the other towns provided with waterworks is said to have been "quite satisfactory." The important sewerage works at Benares are being proceeded with. The Sanitary Board met four times during the year, and had under consideration questions connected with the drainage works in course of construction at Benares; with the question of a water supply for Jhansi, and other matters of a kindred nature. The maintenance of sanitation books in villages, in accordance with the provisions of the Village Sanitation Act, was the subject of inquiry by the Sanitary Commissioner, and it was ascertained that in 22 districts the orders of June 1899 had been carried into effect by the end of the year, while in others steps were being taken to introduce the prescribed records. In two districts, only, no beginning had been made towards carrying into effect the orders regarding these village sanitation books.

12. *Summary.*—The year was not unhealthy, although its death-rate was considerably higher than that recorded in the previous year. Its rainfall was in some respects abnormal. The winter rains were deficient; there was an unusually heavy fall in April and May, and the monsoon set in at the usual time but ceased prematurely. Prices of the staple food grains differed but little from those which ruled in 1898. The most remarkable feature of the year was its birth-rate: this was the highest hitherto recorded. Both cholera and small-pox were less prevalent than usual. Vaccination made good progress, the large increase in the number of infants vaccinated being a specially favourable feature of the season's work. Fevers and bowel-complaints caused a somewhat higher mortality than in the previous exceptionally healthy year. The marked increase in the number of deaths recorded under the heading of "all other causes" seems to need explanation. Until towards the end of the year the Province recorded no indigenous case of plague; but the return in the end of November of three persons from Bombay to their home in a village some twenty miles from Allahabad, was followed by the outbreak of plague among the villagers. The active measures taken to circumscribe the disease were successful. Of important sanitary works the construction of the great drainage system at Benares, still in progress, was one of the chief. Much attention was paid to the maintenance in an efficient state of the waterworks in the nine municipal towns possessing them. The quality of the water supplied by these works, with one exception, is stated to have been quite satisfactory.

No. 4.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of the Punjab for 1899.

The Report has the merit of brevity. It covers only 28 pages, and of these several are taken up with tabular statements. In our Memorandum on the previous year's Report, it was suggested that in future a short paragraph might be devoted to an account of the main meteorological features of the year, and some estimate made of the effect which the weather, the prices of food grains, and the rate of wages earned by the labouring classes, appeared to have exercised on the general health of the population of the Province. We would venture to repeat this suggestion. From the statement given in Appendix F, it is gathered that the average rainfall of the year under report was for every quarter much below the average for the corresponding quarters of the previous ten years. The decrease was most marked in the third quarter, when an average of only 7·77 inches fell, as compared with 17·53 recorded for the third quarters of the previous ten years. The total rainfall for the year under report was only 13·63 inches, as compared with 24·14 in the previous year, and with an average for the ten previous years of 27·84. A decrease of the rainfall to less than half the average would necessarily have important effects on the supplies of food and water for man and beast. The average prices of food grains were generally higher than in 1898. An examination of the table given in Appendix F shows that, whilst the tendency of grain prices was to fall during 1898 from the high rates with which the year began, the tendency in the year under report was in the opposite direction, prices having been lower in the early part of the year, and higher towards its end. This was only what was to be looked for as a result of the deficiency in the fall of rain during the third quarter of the year.

2. The *birth-rate* of 48·4 per thousand of population is the highest hitherto recorded in the Punjab. No doubt the population of the Province has largely increased since the last census was taken. This increased population would yield a greater number of births and, unless calculated on

the increased population numbers instead of on those of the last census, the recorded bi[illegible] would exceed the actual rate. If the increase of the population which has taken place during the last five years be calculated by adding together the numbers by which the births have exceeded the deaths during those years, it will be found that between 1895 and 1899 the population has increased by no less than 1,362,622. And this probably does not represent the whole of the increase. As the Lieutenant-Governor remarked in the review of the Sanitary Commissioner's Report for 1898, great changes in the population are going on in these days in consequence of the construction of railways and canals. But although the high birth-rate can be shown to be in part due to the increase in the population since the last census was taken, it was also no doubt partly due to the better times which set in towards the end of 1897 and continued throughout 1898. A marked rise in the birth-rate seems to be a normal characteristic of a period of prosperity following upon hard times. The effect which increase of the population since last census may have in raising the birth-rate is well exemplified in the case of the Jhang District, which records a rate of 69·1. This extraordinarily high rate is said to be due "to the large influx of people in the district in consequence of the opening of the Chenab colony." Improvement in the registration of vital statistics and the consequent omission of fewer births from the registers may also have had a share in raising the recorded birth-rate. The registered number of births exceeded the registered number of deaths during the year by no fewer than 386,276 or by 18·8 per thousand of population. This may, no doubt, be accepted as an indication that the times are prosperous; but it cannot fail likewise to suggest certain anxieties for the future in a country subject to periodic failure of rain and crops, and with a population largely made up of labouring classes living from hand to mouth.

3. The *death-rate* fell from 31·05 in the preceding year to 29·57 in the year under report. For the same reason that the recorded birth-rate has been shown to be higher than the actual birth-rate, the recorded death-rate can be shown to be higher than the actual death-rate. If the death-rate were calculated on the larger population numbers of the year yielding the deaths, instead of on the smaller population numbers of the last census, it is evident that it would be lower in the former than in the latter case. As a high death-rate ordinarily accompanies a high birth-rate, and as the latter was the highest ever recorded in the Punjab, a death-rate of 29·57 may be regarded as indicating that the year was a healthy one. A reference to the table given in paragraph 21 of the Report will show that, of the total number of deaths during the year, rather more than a third were those of infants under one year of age. Whilst the death-rate for the entire population was only 29·57 per thousand, it was 230 for children under one year of age taken separately. From this it is obvious that the greater the proportion which the number of children under one year bears to the entire population, or, in other words, the higher the birth-rate the higher will be the death-rate. The very high birth-rate of 69·1 per thousand of population in the Jhang District, the highest recorded in the Province, has already been referred to. Accompanying this, in the same district, there is a death-rate of 41·6, also the highest recorded in the Province. Regarding the Jhang District, the Sanitary Commissioner remarks, "The high death-rate is due chiefly (1) to malarial fever brought about by irrigation; (2) to under estimation of the male population." Doubtless these causes contributed to the record of a high death-rate; but unless the birth-rate had been exceptionally high it is probable that the death-rate would not have been exceptionally high. From Annual Form No. IV. appended to the Report it will be seen that, of the 18,152 deaths which were recorded in Jhang no fewer than 6,204 were deaths of children under one year of age. The high birth-rate and the high death-rate of this district would thus appear to be intimately related to each other.

4. *Registration of Vital Statistics* continues to receive much attention. The results of the testing of the entries in the registers by the several agencies show, however, that a considerable percentage of the births and deaths still remains unrecorded. Excepting in the frontier districts, where special difficulties have to be contended against and where persistent efforts are being made to overcome them, the results show that the registration of vital statistics in the Punjab is effected with a close approximation to accuracy.

5. *Chief Diseases.*—Although *cholera* appeared in epidemic form in some districts, the mortality due to it was inconsiderable. Only 1,816 deaths were attributed to the disease, giving a death-rate of 0·09 per thousand of population. The Punjab is outside the endemic area of cholera, and is subjected to destructive invasions of the disease only at long intervals. During the past 33 years cholera deaths have only in three of them caused a mortality of 1 per thousand of the population. In the year under report some evidence is given to support the opinion that the disease was imported into the localities affected by it; but it is mostly of an inexact and inconclusive character. The outbreak in Shahpur, the district which suffered most, followed the arrival from Hissar by train of "a large body of famine sufferers." The conclusion arrived at by the Sanitary Commissioner regarding the conveyance of the disease from Hissar to Shahpur by these sufferers is stated in these words:—"Everything points to the disease being brought with them from Hissar, though cholera was not reported in that district till some days later." On the other hand, the Civil Surgeon is of opinion that cholera was not imported into that district but "originated *de novo*," as a consequence of drinking filthy water. Of the measures adopted with the object of cutting short the outbreaks of the disease, the protection and disinfection of the water-supplies were the chief.

6. *Small-pox* accounted for 5,149 deaths, or 151 more than during the previous year. Municipal towns might have been expected to have been better protected by vaccination than rural areas; but, as a matter of fact, the death-rate in the former was more than double the provincial rate. In the former it was 0·53 per thousand of the population; and in the latter 0·25. The district of Peshawar by itself recorded no fewer than 2,288 small-pox deaths; and of these 770 occurred in the municipal town of Peshawar. On the other hand, the Kangra district "enjoyed complete immunity from small-pox throughout the year 1899-1900." Kangra is the best vaccinated, and Peshawar the least vaccinated district in the Province; the former records no death from small-pox; the latter records not far short of as many deaths as all the other 30 districts together. The result of the season's vaccination work was eminently satisfactory. Without increase to the strength of the vaccination

iment, which remained the same as in the previous year, there was an increase in the number ses of primary vaccination of 82,980, and in the number of cases of re-vaccination of 19,226. The percentage of successful cases was practically the same in primary vaccination cases as in the previous year—94·68 in the year under report and 94·84 in 1898-99. In re-vaccination cases a percentage of 62·55 was recorded, as compared 58·80 in the previous year. These satisfactory results the Sanitary Commissioner attributes to the "work being done in a more systematic way than in previous years." Judging from the statement given in paragraph 13 of the Report, the work of the vaccinators was subjected to very thorough scrutiny. Of a total of 744,917 primary vaccinations, no fewer than 685,851 were examined by the several supervising agents, and 114,532 of the total of 198,152 re-vaccinations. Experience has shown that the closest supervision is absolutely essential to prevent falsification of their records by some of the vaccinating staff. The Sanitary Commissioner writes:—"I would remark here that owing to such thorough inspection, the fudging of returns by vaccinators has been reduced to such a minimum that only two reports of irregular work were brought to my notice this year." Animal lymph was chiefly used during the year, and gave a percentage of 99·31 successful cases in primary vaccination. Human lymph, which was used in only 19,571 operations, gave a percentage of 99·37 successful cases, or almost the same as animal lymph; whilst vaseline lymph was used in 158,976 cases, and gave a percentage of 96·81 successful cases. But whilst vaseline lymph gave the lowest percentage of successful cases in primary vaccination, it gave a higher percentage than either animal or human lymph in re-vaccination. Some interesting experiments were commenced by Captain Wilkinson, the Deputy Sanitary Commissioner, with a view to ascertain the degree of protection conferred by vaccination with vaseline lymph paste; but, unfortunately, he was ordered on plague duty before he had time to complete these experiments. The Sanitary Commissioner says "Captain Wilkinson was unable to do more than make so few experiments as to prove nothing"; but he proposes that these experiments should be repeated. A return is given showing the number of children under one year of age in towns available for vaccination, and the number of successful operations performed on them during the year. From this return can be ascertained at a glance the extent to which vaccination is practised among the infant population of each town of the Province.

7. The mortality from *fever and bowel complaints* was less than in the previous year, and also less than the average for the previous five years. This result was, doubtless, as the Sanitary Commissioner observes, due to the comparative dryness of the year. The rainfall during the third quarter of the year amounted, as already stated, to only 7·77 inches against an average of 17·53 for the preceding ten years. In the Jhang District a death-rate from fever of 24·06 per thousand of population is recorded, as compared with the provincial average of 18·57. This high rate, the Lieutenant-Governor says, may or may not be due to irrigation from the recently opened Chenab Canal, and adds that no decision can be come to on this question until the figures of the next census are available.

8. Beyond stating the number of deaths reported to have occurred from *plague*, no account of the progress of that disease during the year in the Punjab is given in the Report under review. The Sanitary Commissioner has not taken up the subject, he says, because plague is reported on by the Chief Plague Medical Officer. According to the figures given in paragraph 29 of the Report, the total deaths from plague numbered only 227. The Lieutenant-Governor directs that in future the Sanitary Commissioner should give an account of the progress of plague in his Annual Report. It seems only fitting that the health report of the Province should contain some account of the progress of a disease which has given rise to so much anxiety and trouble.

9. *Sanitary Works.*—The expenditure under the heads of *drainage* and *water-supply* in municipal towns shows a large increase over that of the previous year. Under the head of drainage and sewage the amount expended increased from £6,460 to £12,956, or to more than double; whilst under the head of water-supply it increased from £11,054 to £12,470. This shows that substantial progress is being made in the promotion of sanitary works of a permanent character. An examination of Statement XI., given in the Appendix to the Report, seems to show that if much has been, and is being done in promoting sanitary improvement in municipal towns, the condition of portions of some even of the chief cities is still far from perfect. Quoting from the very useful statement referred to, it is found under the head of "Drainage," that in Delhi, the largest city in the Province, "many of the old underground drains which become blocked frequently, at all times a frightful nuisance, still exist. All these require to be replaced by surface drains. There are no drains at all in Sabzi-Mandi, Sadar-Bazaar and Paharganj districts, and drains are urgently required." But against such defects are to be set all that has been done in providing Delhi with a good water-supply and improving its drainage. The description given of Lahore, the capital and second largest city in the Province, shows that its sanitary condition approaches more nearly to the standard set up for western cities. The death-rate recorded for Delhi was 36·67 per thousand of its inhabitants, and for Lahore 32·68. The average death-rate of Delhi for the previous ten years was 40, and of Lahore 36 per thousand of its population. These figures indicate a distinct improvement in the public health of the two principal cities of the Province. The endeavour made by the Lieutenant-Governor to enlist the interest of the rural population in the improvement of the sanitary condition of their villages by the grant of rewards to the village communities showing the best results, have not, it is said, been as yet marked. This need not be wondered at in the case of people so conservative as those of India. But without the co-operation of the people themselves the effectual sanitation of the 37,602 villages of the Province could hardly be regarded as feasible; and the offer of inducements of the nature of that held out by the Government seems a reasonable means of helping to secure such co-operation.

10. *Summary.*—The year was exceptionally dry owing to the failure of the monsoon. The birth-rate, 48·4, was the highest hitherto recorded. The death-rate was 29·57, and the deaths were fewer than the births by 386,276, this number representing the natural increase of the population for the year. The increase of the population since last census, on the figures of which the birth and death-rates are calculated, has raised the recorded above the actual rates. The registration of vital statistics continues to receive much attention, and, except in the frontier districts, may be assumed to be

approximately accurate. The year was healthy. Cholera was accountable for a death-rate [illegible] 0·09 per thousand of population. Small-pox was severe only in the Peshawar District, in which it caused not far from half the total number of deaths recorded in the Province. Peshawar is the least vaccinated district in the Punjab. The Kangra District, which is the best vaccinated district, did not record a single small-pox death during the year. Vaccination made very satisfactory progress, the number of primary operations having increased by no fewer than 82,980, and the re-vaccinations by 17,266 as compared with the previous year's numbers. Fevers and bowel-complaints were less fatal than usual, owing, no doubt, chiefly to the exceptional dryness of the year, and especially of its third quarter. The mortality from plague was inconsiderable: only 227 deaths were reported as due to it. There was a large increase in the expenditure by municipalities on permanent works of sanitary improvement. The inducements held out by the Government to the village communities with the object of securing their co-operation in the cleansing of their villages, have not, it is stated, led to any marked results. But progress must be slow amongst so conservative a people, and it is too soon yet to despair of some degree of success in the future.

14th May, 1901.

No. 5.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Burma for 1899.

According to the concise summary given by the Sanitary Commissioner, the year under review had a slightly higher rainfall, with higher mean humidity and lower mean maximum and minimum temperatures than its predecessor. The harvest was good throughout the Province and prices somewhat lower than in the previous year. Owing chiefly to increased prevalence of cholera, small-pox, and bowel-complaints, the death-rate was higher than in the previous year; but, on the whole, the year under review was a healthy one.

2. This year, again, the population figures dealt with in the Report have undergone a slight alteration owing to such changes, for example, as the exclusion of a portion of the Mergui district from the area under *registration*. Thus altered, the population figures are now 4,461,027, as compared with 4,510,697 in the previous year. Although a commencement has been made with the registration of vital statistics in certain towns and selected districts in Upper Burma, the Sanitary Commissioner has, wisely we think, refrained from incorporating them with the statistics of Lower Burma, and has briefly reviewed them separately, "as it has been considered undesirable to vitiate the returns of the Lower Province by their inclusion." The Government has decided not to attempt, for the present, the registration of births in Upper Burma. "Experience in Lower Burma," it is stated, "shows that the people can be brought to understand, more or less, the reason for registering deaths, but not that for registering births." After the village headmen have been for some years practised in the work of registration of deaths, the Lieutenant-Governor thinks the registration of births may also be undertaken with some hope of success. But whatever the method chosen for introducing registration of vital statistics, whether by making a commencement with the registration of deaths alone, or with registration of births and deaths together, experience in the Indian Provinces has shown that it is mainly by "constant inspection and patient instruction" that progress towards the attainment of approximate accuracy in the collection and record of vital statistics can be effected. In the words of the Government review, too much stress cannot be laid on the importance of achieving accuracy in the returns. The marked improvement in registration which has taken place under the persistent attention devoted to it, more especially during recent years, may be accepted as implying that improvement will be continuous so long as this attention is not relaxed.

3. The recorded number of *births* increased from 153,838 in the previous year to 165,229 in the year under review, giving a ratio of 37·04 per thousand of population, as compared with 34·11 in 1898, and with 31·82 in 1897. The contrast between the ratios recorded for some of the urban as compared with rural areas is striking. The Arakan urban circles record a birth-rate of only 17·31, whilst the rural areas of the same division record a rate of 34·99 per thousand of population. But the constitution of the population of the Arakan towns and country goes far to account for this difference. Whilst the urban population of the division, numbering 44,017, consists of 32,711 males to only 11,306 females, the rural population of the same division, numbering 608,036, consists of 314,185 males to 293,851 females. In the case of the towns, whilst there are approximately three males for every one female, in the case of the country the proportion of the sexes does not widely differ. In other cases where the disproportion is not so great as in Arakan, the wide divergence between the urban and rural birth-rates is probably due to defective registration. It has often been remarked that the greater the disproportion between the recorded number of births of male as compared with female children in India, the greater will generally be found to be the inaccuracy of registration. In the Arakan division the births of 109 male children were recorded against every 100 of female children. In Minbu division the proportion was only 101 of the former to 100 of the latter. But much importance need not be attached to such figures; in the previous year there were 109 male to every 100 female births in the Minbu division. In short, the more the ratios of births and deaths for the different areas are examined, the oftener will it be found necessary to fall back on defective registration to account for some of the anomalies which they indicate.

4. Along with an increase of the birth-rate there was a corresponding increase of the *death-rate*. This latter rose from 26·13 per thousand of population in the previous year to 27·30. The increase in the number both of births and deaths was, no doubt, partly due to increase of population, and also probably in some degree to improved registration. The increase of the death-rate would also be

ed by the higher birth-rate, in other words, by a larger proportion of the population being of e at which death is most likely to take place. Without apparently any purpose of furnishing mple of the movement of the death-rate, upwards or downwards, with corresponding move- of the birth-rate, the Sanitary Commissioner writes :—"The Irrawaddy division, which returned ighest birth-rate, also returned the highest death-rate (29·12); and similarly the lowest death-rate 7) was recorded for Minbu, as was also the lowest birth-rate." Male infants died at the rate of 9 per *mille* living, and female infants at the rate of 212·77. It is thus evident that the higher proportion of infants which the population contains, in other words, the higher the birth-rate the her, ordinarily, will be the death-rate. "This high death-rate amongst children," writes the nitary Commissioner, "is not peculiar to Burma, but is more or less general throughout India, specially where insanitary conditions, ignorance, and poverty prevail, for infants and young children re far more sensitive to unhealthy surroundings and morbific influences generally." He might have dded that a high death-rate amongst infants is a general feature of vital statistics all the world over, especially under the conditions he mentions.

5. *History of the Chief Diseases.—Cholera*, which, in the previous year, had been less fatal than usual in Burma, as throughout India, increased in prevalence during the year under report. Whilst n 1898 the deaths attributed to it numbered only 2,972, they increased to 4,942 in 1899, giving a ratio f 1·11 deaths per thousand of population, as compared with the ratio of ·66 in the previous year, and of ·96 the mean for the ten years 1889–98. As in the previous year, deaths due to cholera were returned during each month of the twelve. Of 16,757 villages under registration, 1,093 recorded deaths from cholera, and the average number of deaths in each of these villages due to the disease was five. The Sanitary Commissioner advances no theories of his own to account for the origin of the disease in the different localities in which it made its appearance ; and he states that, "as regards the etiology of cholera none of the district reports throw any light upon the origin of first cases." As usual, endeavours have been made to prove importation of the disease into localities affected by cholera ; but, in the opinion of the Sanitary Commissioner, in no instance has such importation been conclusively proved. The history given of the first attacks in jails is interesting. The exact facts, as far as they could be ascertained in each case are stated. Beyond the circumstance that the disease was prevalent among the free population in the neighbourhood of the jails affected, no direct connection was in any instance traced between the first case of the disease inside a jail and a case outside. Colonel Little thus sums up the history of cholera in the jails of the Province during the year : "Here we have eight groups of population under constant supervision, well-fed, well-clothed, and living under the best possible sanitary conditions, with every precaution to prevent the importation of disease, and yet, in spite of all, cholera finds an entrance and the cause of its appearance cannot be traced." Many medical officers are convinced that cholera is solely a water-borne disease, and that it is generally possible to trace outbreaks to the use of water containing the *comma bacillus*. The medical officer of the Moulmein jail reports that, though the disease was apparently imported into the jail from outside, yet "the manner of its entrance remains as mysterious as in former years, in view of the fact that every possible or conceivable precaution had been taken to prevent its entrance. The drinking water, obtained from a closed tunnel and then boiled, could not have caused it ; and it is difficult to see how it could have arisen from the food, and why one man should be attacked and several hundreds escape, living under the same conditions, and eating the same food and drinking the same water."

6. From *small-pox* a death-rate of 1·32 per thousand of population was recorded as compared with 1·07 in the previous year, and with a mean of ·56 for the ten years ending 1898. Too much importance need not, however, be attached to this apparent increase during a period when the registration of vital statistics has been steadily improving in efficiency. The importation of small-pox into Burma and its dissemination throughout the Province are attributed to the unprotected coolie immigrants, who arrive in large numbers during the harvest season for employment in reaping the rice crop. The practice of inoculation is also credited with a share in establishing foci from which the disease may be spread. A somewhat surprising statement is made in paragraph 62 of the Report. "Amongst Europeans and Eurasians in the town of Rangoon there were 139 attacks and 37 deaths from small-pox, which gives a death-rate to attacks of 26·6 per cent." One would have expected that these comparatively educated classes, running the risks of contracting the disease in Rangoon, would of their own action have taken care to be fully protected against attack by undergoing re-vaccination. After much discussion, the Burma Vaccination Law Amendment Act has been passed, and the Lieutenant-Governor trusts that the provisions of this Act will result in checking, to some extent, outbreaks of the disease, such as occurred in Rangoon during the year under report. The Act gives power in Rangoon Municipality, and in the other municipalities to which the Act may be extended, to require an unprotected person to be vaccinated ; and provides, moreover, for the compulsory vaccination of inmates of lodging-houses or coolie barracks. During the year under review, the strength of the vaccination staff of the Province was increased by the appointment of a few additional vaccinators and two inspectors of vaccination. As a consequence, there was a corresponding increase in the number of successful primary operations from 415,836 in the previous year to 432,622 in the year under report. At the same time, the number of re-vaccinations increased from 27,258 to 34,125, of which latter number 20,035 were recorded to have been successful. The percentage of successful cases in primary vaccination, 94·71, remained the same as in the previous year ; whilst there was a slight decline in the percentage of re-vaccination cases from 59·55 to 58·72. Could the accuracy of these figures be relied on, the season's work might be regarded as fairly satisfactory ; but unfortunately this is not the case. "It is very evident from district reports," writes the Sanitary Commissioner, "that there is a considerable amount of false work returned by vaccinators ; and District Medical Officers' inspections show that there is an appreciable amount of utterly incompetent vaccination, as well as a large proportion of second-rate work." Closer supervision is the remedy ; and to secure this the inspecting staff, as the Lieutenant-Governor observes, will have to be greatly strengthened. Humanised lymph is still used in Burma, and the results obtained from arm-to-arm vaccination are considered to have been good ; but the Sanitary Commissioner says there are obvious objections to this method of operation, and orders have issued that

it must be discontinued as far as possible. Complete success has not yet been attained preparation of glycerinated vaccine lymph at the Taunggyi depôt; and the partial failure lymph sent out for use seems to have been due to the free use of the perchloride of mercury antiseptic during the process of collecting it from the calf. This antiseptic, the Sanitary Commi thinks, whilst destructive of putrefactive germs, has a similar effect on the vitality of the v germs which it was intended to protect. It might be found expedient to follow the meth procedure in the preparation of glycerinated vaccine lymph which Colonel Campbell has fou yield so remarkably successful results in Assam, a province with a climate, it is believed, be some resemblance to that of Burma. The Lieutenant-Governor takes exception to the length of Vaccination Report. As he points out, a Report on Vaccination is only called for every third yea for intermediate years the returns should merely be accompanied by a brief note for their elucidation At the same time, the report now furnished, although long, is both interesting and useful.

7. The number of deaths attributed to *fevers* was somewhat less than the number recorded in th previous year. The ratio of deaths due to fever in urban areas is, as usual, less than that in rura areas. The Sanitary Commissioner thinks the explanation is to be found in the circumstance tha dwellers in the country are more exposed to malarious influences than residents in towns. Bu there are grounds for the belief that the difference between the ratio of 8·12 per thousand of th population attributed to fever in towns, and the ratio of 11·97 in rural areas, may to some exte be due to differences in diagnosis. For, if the returns of mortality are examined, it will be seen that, whilst towns show a much lower ratio of mortality from fevers than rural circles, they show, on the other hand, a much higher mortality under the heading of "other causes" than the latter. The death-rate in urban circles under the head of "other causes" is stated in paragraph 28 to be 18·63 per *mille* of population; the death-rate under the same heading for districts and towns combined is stated in paragraph 43 to be 11·33. The presumption that these figures suggest is, that many of the deaths attributed to fever in rural circles are recorded under the head of "other causes" in towns. But whilst registration is still so defective, too much weight must not be attached to reasoning of this nature. The sale of quinine is being persevered with, and the Lieutenant-Governor thinks the Sanitary Commissioner should consider whether the services of district vaccinators should not be utilised in the distribution of the drug. The mortality from *dysentery* and *diarrhœa* has remained nearly constant during the past two years, and seems to call for no special remark.

8. *Sanitary Works.*—In Burma, as in the Indian Provinces, "the main obstacle," to quote from the Government review of the Report, "to the improvement of sanitation even in the large municipalities is the lack of funds." No sanitary work of importance was undertaken during the year, but several preliminary surveys and experiments were carried on with a view to arriving at a decision regarding the kind of scheme most suitable for adoption in various towns. The postponement of useful sanitary improvements may be regrettable, but delay is preferable to hasty or ill-considered action, leading to defective results. Without the co-operation of the people of the country, little or lasting advance in sanitation can reasonably be hoped for; and before such co-operation can be secured the people will have to be educated sufficiently to enable them not only to understand and appreciate, but to be willing to pay for, the benefits to health and comfort which follow upon sanitary improvements. This education is likely to be a somewhat slow process; but without it, what of progress is made under official pressure is pretty certain to cease so soon as this pressure is relaxed. Over-activity in the promotion of sanitary improvement may occasionally lead to undesirable results. Regarding one of the districts of the Province, we read:—"Most of the rules are said to be strictly followed; in fact, some of them, especially that in connection with the cleaning up of villages, was so rigorously imposed that some officers would appear to have been guilty of harassing the villagers, headmen being ordered to fine the villagers by the score. This was promptly stopped and some of the fines refunded." Much, however, can be, and often is, done by District Officers to induce the people to cleanse their towns and villages, and especially to protect their water supplies from pollution, without having recourse to other stimulus than advice and encouragement.

9. *Summary.*—The year was, on the whole, healthy. Its rainfall was slightly higher than that of its predecessor, its humidity greater, and its mean maximum and minimum temperatures lower. The harvests were good and grain somewhat cheaper than in 1898. Registration of vital statistics is improving in Lower Burma, and is being gradually introduced into Upper Burma, although for the present only deaths are being recorded in that part of the Province. The birth-rate of the year increased from a ratio, per *mille* of population, of 34·11 in the previous year to 37·04; and along with this increase the death-rate rose from 26·13 to 27·30. The increase of the death-rate was partly due to greater mortality from cholera, small-pox, and bowel complaints; and doubtless, also, increase of population and a higher birth-rate. Cholera was more fatal than in the preceding year, when the disease was in comparative abeyance throughout the Indian Empire. An interesting account is given of the appearance of the disease in the jails of the Province. In no instance could the mode of ingress of cholera into a jail be exactly determined. Small-pox mortality was greater than in the previous year. Its importation into the Province is attributed chiefly to the coolie immigrants, who arrive annually in great numbers for employment in reaping the rice crops. Vaccination, judging from the returns, made fair progress; but doubts are thrown on the accuracy of these returns. The glycerinated vaccine lymph prepared at the Taunggyi depôt has not proved so successful as could have been desired; its partial failure appears to have been traced to the use of perchloride of mercury as an antiseptic in the process of collecting the lymph from the calf. Fever mortality was less than in the previous year. Two isolated cases of plague were removed from vessels arriving in Rangoon; but the Province has, so far, escaped a visitation of the disease in epidemic form. Lack of funds in Burma, as in other Provinces, retards sanitary improvement. No sanitary work of importance was undertaken during the year; but several preliminary surveys and experiments were carried out with a view to arriving at a decision regarding the kind of scheme most suitable for adoption in various towns.

13th May, 1901.

No. 6.

RANDUM by the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER of the CENTRAL PROVINCES for 1899.

Like its predecessor, the year under report was a very healthy one. Its most important climatic feature was the failure of its rainfall. The immediate effect of this failure was to lessen the prevalence of malarial diseases during the last quarter of the year; its calamitous effect upon the crops and the resulting consequences to the public health of the Province will come to be recorded in the history of the following year. Although scarcity deepening into famine made itself felt during the closing months of 1899, the beneficial influence on health of the exceptional dryness of those months more than counterbalanced the injurious effects of scarcity, so that, instead of rising, the death-rate fell somewhat below that recorded during the corresponding months of the preceding very healthy year, and considerably below the mean of these months during the decennial period 1881-90. For the Province as a whole the mean rainfall of the year under report was only 24·4 inches, or less than half the mean of 51·73 for the past 33 years. In some districts the deficiency was very great. In Nagpur only 13·21 inches fell, as compared with a mean of 42·72 for the preceding 33 years; in Betul 10·72 as compared with 41·02; and in Khandwa 8·07 as compared with 30·52. This last was "the smallest ever recorded" in the Khandwa district. Considerable space is devoted to an account of the weather and crops. The consequences of the rain failure differed only in degree in the several districts. In Chindwara "the total failure of the monsoon brought on an unprecedented famine throughout the district, and relief works on a large scale were opened to save the people from starvation." In other districts the accounts given are of a similar nature.

2. The *birth-rate* recorded for the year was (excluding Chhatisgarh Zamindaris) 47·35 per 1,000 of population, against 29·91 in the previous year. As suggested in last year's memorandum the inclusion of the returns for the *zamindaris* had better have been deferred until after the taking of next census, as otherwise the vital statistics for the final three years of the inter-census period 1891-1900 cannot properly be compared with those of the first seven years of that period. The inclusion of the *zamindari* returns and the use of the estimated population figures for the calculation of births and deaths are liable, unless care be exercised, to lead to error in instituting comparisons between the statistics of the present and those of preceding years. In paragraph 6 of the Report a table is given showing the birth-rates in the different provinces of India for the years 1898 and 1899. In this table the Central Provinces are given the third place on the list with a birth-rate of 47·35; but by an oversight the death-rate has been substituted for the birth-rate in the case of the North-Western Provinces. Except for this mistake the North-Western Provinces with their birth-rate of 48·09 would occupy the third, and the Central Provinces the fourth place. Similarly, in the table in paragraph 25, the North-Western Provinces are given the last instead of the seventh place in the list, the birth-rate, 48·09, taking the place of the death-rate, 33·19. During the year every district showed an excess of births over deaths, the total excess being equal to 19·26 per 1,000 of population. A comparison of the birth-rates of the two successive years 1898 and 1899 month by month, shows that the high rates which began to be recorded in the former of these years in September continued without check until October of the latter, after which they fell away during the last three months of the year. The proportion of male to female children born was 105·29 of the former to 100 of the latter. This proportion varied in the different districts from 101·63, the lowest, to 111·68, the highest. The provincial proportion of 105·29 may be accepted as approximately normal, and some indication of good registration.

3. The *death-rates* of 31·34 and 28·81 noted in paragraph 13 of the Report are those got by using in calculating them out, not the census population figures, but those "determined by the natural increase or decrease of the population" since last census was taken. On the other hand the birth-rate, 47·2, noted in paragraph 3 of the Report, is got by using in calculating it the census population numbers and not the numbers determined by the natural increase or decrease of the population since the census was taken. There is no objection to the use of either set of population figures in calculating birth and death ratios, but obviously one set should not be used when birth-rates are calculated, and a different set when death-rates are calculated. The death-rates, "as calculated on the population according to census enumeration," are also given in the table side by side with the rates mentioned, and confusion would have been avoided had the former been noted in paragraph 13, in accord with the mention of the birth-rate, similarly calculated in paragraph 3. The death-rate of 28·09, or that obtained by excluding *zamindaris*, and using in its calculation the last census population figures, is the rate best suited for comparison with the rates for the previous years. The corresponding rate for the exceptionally healthy year 1898 was 24·30, and for 1897, a famine year, 69·34, whilst the mean annual death-rate for the period 1891-95 was 33·76. The total number of deaths during the year under report was "below the total of all years in the past decade except 1893 and 1898." One cause of the increased mortality as compared with that recorded in 1898 was the increased birth-rate. Not only was a larger addition made to the population of those in whom the liability to death is the greatest, that is to say, of infants, but the death-rate amongst these was higher during the year under report than in the preceding year. In 1898 there were 284,176 births registered; in the year under report 449,895. In the former year 59,845 infants died, giving a death-rate per 1,000 of 210·58; in the latter 103,022 infants died, giving a death-rate of 382·99 per 1,000. The latter rate, however, does not represent with even approximate accuracy the real death-rate amongst children under one year of age during the year; for, whilst the number of children of that age was only 268,732 in the census year, the number of births in the year under report was 449,895. If the former numbers are employed in making the calculation the death-rate will be found to be, as stated, 382·99; if the latter numbers are used the death-rate will be 229·99. Obviously, the death-rate

is more correctly represented by using the number of births recorded during the year for w[illegible] calculation is made, than the number of children under one year of age at the time of taking [illegible] census. If the death-rates recorded for rural areas are contrasted with those recorded for m[illegible] towns in which registration is compulsory, it might be concluded that the towns are muc[illegible] unhealthy than the rural villages, in spite of the organised system of sanitation established [illegible] former. The death-rate recorded for rural areas is 27·53, and for municipal towns 34·98. [illegible] probable, however, that, as pointed out in the Government review of the Report, the higher deat[illegible] recorded in these towns is more likely to be due to greater accuracy in registering deaths tha[illegible] greater unhealthiness. Satisfactory results do not appear, so far, to have followed the attempt m[illegible] to improve the record of the causes of death by requesting civil surgeons to make inquiries regardi[illegible] these causes. "As to the investigations made by the civil surgeons, weeks or months after th[illegible] occurrence, I regard them," writes the Sanitary Commissioner, "as almost useless."

4. *General History of the Chief Diseases.—Plague* is given the first place on the list, though as a matter of fact neither this, nor cholera, nor small-pox was the cause of a high mortality during the year. The total number of deaths attributed to these three diseases combined was only 1,724 out of a total from all causes of 266,930. Only two imported cases of plague, which proved fatal, were reported. Both came from Bombay. The remaining 582 fatal cases were indigenous, and were limited to the two districts of Nagpur and Wardah. During the preceding year, the first in which plague as a cause of mortality finds a place in the returns, the deaths recorded under this head were only 131. There has thus been a considerable increase in the prevalence and fatality of the disease in the year under report, which augurs ill for the success of the measures devised with the object of staying its further progress. It might be comparatively easy to deal with infected villages by causing them to be temporarily evacuated, but when the disease has secured a foothold in a city like Nagpur such a method of treatment becomes practically impossible.

5. The quiescence of *cholera* during the two years succeeding the destructive epidemic of 1897, when 57,131 persons were swept off by it, is a remarkable phenomenon, and one the explanation of which has not been attempted. In the year immediately following the great epidemic years 1896-97 only seven deaths were attributed to cholera, and now in 1899 only 76. But the circumstance that of these 76 cases no fewer than 64 occurred in the last month of the year seems to point to a recrudescence of the disease, and to the probability of its increased prevalence in the following year.

6. *Small-pox* has again been in comparative abeyance, only 1,064 deaths having been caused by it. As in the case of cholera, however, the occurrence of 155 deaths from small-pox in December seems to point to the probability of renewed activity of the disease in the following year. No doubt a re-accumulation of unvaccinated persons has been going on since the three severe epidemics of 1895-97 killed off, or protected the majority of those not previously protected by vaccination, inoculation, or an attack of small-pox. Vaccination made satisfactory progress during the year 1899-90. Although re-vaccinations decreased in number by no fewer than 16,311, there was an increase of 65,672 primary vaccinations as compared with the numbers recorded in the previous year. The only district in which there was a marked decrease in the number of primary operations was Nagpur, and it is explained that this was due to the vaccination staff having been employed on plague duty up to the 16th January, 1900. There was a decrease of no fewer than 11,321 primary vaccinations in this district—another illustration of the unfortunate consequences to the work of vaccination resulting from the diversion, so frequent during late years, of the vaccination staff to assist in carrying out plague measures. One of the most satisfactory features of the year's work is the large increase in the number of infants successfully vaccinated. In the previous year this number was 200,587, and in the year under report 263,584. The total number available for vaccination in the latter year was 353,992, so that there would thus remain an unprotected residum of 90,408 children under one year of age. The percentage of successful cases for the Province as a whole was 96·50 in primary operations, and 82·73 in re-vaccination. The latter percentage is, as usual in the Central Provinces, very high, and in striking contrast with that of 17·2 recorded in the adjoining province of Berar. Animal lymph was used in 276,137 operations in the various districts, according to the table given in paragraph 40 of the Report, and to supply lymph for these no fewer than 9,812 calves were inoculated. From this it would appear that each inoculated calf supplied, on the average, lymph for only about 28 children. This is less even than the number of children vaccinated from each calf in Madras city, where it was on the average 56 when used direct from the calf, and 363 when "glycerinated." In Assam, where calf lymph is preserved by admixture with glycerine, each calf supplied, on the average, sufficient lymph to charge 1,047·46 capillary tubes. If the Assam method of preparing calf lymph can be successfully introduced into the Central Provinces the resulting convenience and saving of labour and expense will be great.

7. The death-rate credited to *fevers* was 16·17 per 1,000 of population. It was thus slightly less than the rate recorded for the previous year, when it was 16·40, and less than half the rate for 1897, when it was 40·98. An examination of the mortality returns show that remarkably low death-rates from fever were recorded during the last months of the year. This was doubtless, in part at least, owing to the unusual dryness of these months consequent upon the scanty amount and premature cessation of the rainfall. The same cause doubtless contributed also to a low mortality from bowel complaints during the year. The death-rate of 1·25 attributed to *dysentery* and *diarrhœa*, though slightly higher than that recorded during 1898, was below the decennial mean of 1·41. There can be little doubt, however, that the real death-rate from these diseases was higher than the figures would indicate.

8. *Sanitary Works.*—Considerable progress was made in providing the more important towns with new waterworks and in improving the water supplies already in use. The new waterworks at Wardah have been opened, and those at Bhandara were approaching completion at the end of the year. A succession of adverse seasons, necessitating enormous expenditure in relieving the distress arising from famine, and in carrying out measures with the object of protecting the

against plague, had no doubt crippled the finances of the municipalities, and led to tponement of many useful sanitary projects. Important and much needed drainage works progress in the city of Jubbulpore. The need for a thorough system of drainage for the f Nagpur is also fully recognised, but the work is delayed owing to want of funds. The uction of a water supply into a town, if not accompanied by a drainage system capable of ing the water after it has served its uses, may render the last state of that town, from a n point of view, worse than the first. The Village Sanitation Act was extended to two e villages during the year under report, bringing the total number under the Act up to 40. perusal of the Sanitary Commissioner's remarks on the results following the introduction of e Acts into these 40 villages, leads to the conclusion that, owing to various reasons, the provisions of the Act have not been enforced with much vigour, or indeed, in some cases, enforced t all during the year. For example, in the Jubbulpore district :—"The Act has been notified as being in force in nine villages of the district, but owing to the succession of bad seasons no steps have been taken to apply its provisions as yet." In consequence of the prevalence of famine the Sanitary Board met but once during the year. As was only to be expected, "the expenditure on village sanitation fell very low. On account of the scarcity local subscriptions could not be realised, and the District Councils also could not provide in full the amounts they had allotted in their budget." The preparation of sanitary maps had been so far completed that it was proposed to commence the registration of vital statistics according to sanitary circles or units with effect from the 1st January of the year under report. "In view, however, of plague in the provinces and an empty treasury, it was decided by the Chief Commissioner that the introduction of the new system should be postponed." As with many other schemes, that of filling up Village Inspection Books has been much retarded during recent years of unusual stress. The energies and resources of the Administration have been strained to the uttermost in combating famine, and in carrying out measures for protecting the Province against plague.

9. *Summary.*—Like its predecessor, the year was healthy. Its most important meteorological feature was the failure of the rainfall. This failure did dot injuriously affect the health of the Province up to the end of the year. On the contrary, the scanty rainfall had, there can be little doubt, the effect during the concluding months of the year of lessening mortality from malarial diseases. The birth-rate was the highest recorded since 1881. The number of deaths was less than in any year of the decade excepting 1893 and 1898. The deaths from plague increased from 131 in the previous year to 584. Cholera was again in almost complete abeyance, only 76 deaths having been attributed to it. From small-pox the mortality was also again low, but the disease showed signs of fresh activity towards the end of the year. Vaccination made satisfactory progress. Animal vaccine lymph was largely used, but the number of calves required for the supply of lymph seems to have been excessive, no fewer than 9,842 having been inoculated for this purpose. The Province enjoyed unusual exemption from fevers and bowel complaints; the consequence, it is believed, of the exceptional dryness of the year, and especially of its last quarter. The limited funds available for sanitary works were expended chiefly in improving water supplies and drainage.

14th May, 1901.

No. 7.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Assam for 1899.

Accepting the observations taken in the three selected districts for which observations are recorded, as representing the general meteorological conditions which prevailed in the Province, the year under report appears to have been an unusually cool one. In two of the selected districts the rainfall was, in the one, very much greater than the average; and in the other about or slightly above the average; whilst in the third it is stated to have been, excepting in 1898, the lowest on record. Accompanying these weather conditions there were good harvests and cheap food supplies. Judged by its record of mortality the year was a comparatively healthy one.

2. "No change occurred in the areas in which vital statistics were collected, but the returns of Kohima station, and the selected areas in the Garo Hills have, for the first time, been included in the provincial returns." The population numbers of last census, 5,050,590 are those on which ratios of births and deaths still continue to be calculated. No doubt these figures have ceased to represent with accuracy the present population of Assam. If the population has increased since last census was taken, this must be due to immigration, and not to the excess of births over deaths, that is to say, to "natural increase." An examination of the returns shows that, whilst for the ten-year period 1887-96 the average annual number of births recorded was 148,725, the average annual number of deaths was 149,407. In the three years 1897-99, taken together, the deaths exceeded the births by over one hundred thousand. But too much need not be made of these figures whilst the registration of births and deaths remains, as it still is, imperfect. Assuming, however, that births and deaths are recorded with equal inaccuracy, it would appear that there has been not only no "natural increase," but a decrease of the population numbers since last census was taken. Possibly this decrease may have been more than compensated for by the annual immigration of labourers for employment on tea estates. The coming census may be expected to clear up such uncertain points, and to show definitely whether, and to what extent, the population has increased or decreased during the preceding 10 years. The Chief Commissioner reiterates the caution that the figures of the returns

are nearly everywhere incomplete. He is of opinion that conclusions of a scientific value [illegible] be drawn from them for comparative purposes, and that even in this respect inferences are [illegible] to be mistaken.

3. The *birth-rate* shows a marked increase over that recorded for the previous year, and li[illegible] over the average for the 10 years ending 1896. Still, a recorded birth-rate of 35·45 during a y[illegible] remarkable fecundity throughout India cannot represent the real birth-rate, which when norm[illegible] estimated to be not less 48 per 1,000 of population. Excepting in the Madras Presidency, where r[illegible] tration is still very defective, the Assam birth-rate is the lowest recorded in any of the chief Ind[illegible] Provinces for the year under report. That the recorded birth-rate is largely a question of the great[illegible] or less efficiency of registration seems probable from an examination of Table 2 of the Report. O[illegible] the six districts of the Brahmaputra Valley only one returns a birth-rate exceeding 40 per 1,000 of it[illegible] population. The district of Goalpara records a rate of 41·43; and Nowgong a rate of only 21·01. Th[illegible] Goalpara district is the only one of the six in which registration of births and deaths is affected by[illegible] paid village watchmen, "with the result," as stated in last years' *memorandum*, "that the work is[illegible] more efficiently performed than in any of the other districts of the same group." An additional[illegible] reason assigned in a previous report for the more complete record of vital statistics in Goalpara wa[illegible] the great interest taken in registration by the Superintendent of Police of that district. Such facts[illegible] seem to lead to the conclusion that in Assam the birth-rate recorded in different districts of the[illegible] Province varies in accordance with the greater or less efficiency of the agency entrusted with the collection and record of vital statistics. In his report for the year 1895, the Sanitary Commissioner wrote:—"There is little doubt that in 1895 not less than 30 per cent. of the births in this Province were not registered." Registration has improved since that remark was made; the birth-rate for 1895 was 31·00; whilst for the year under report it is 35·45. Yet the latter figures fall very far short of those which are estimated to represent the normal rate per 1,000 of population.

4. The *death-rate* was the lowest recorded during the five years ending 1899, and was, at last, below the birth-rate. The number of deaths registered was 156,595, giving a ratio per 1,000 of population of 31·01 as compared with 179,027 births, and a birth-rate of 35·45. Instead, therefore, of the deaths being in excess of the births, as in the two preceding years, by over 100,000, the births exceeded the deaths by 22,432. But there can be no question that the number of deaths recorded is far below the actual number. In a year with a high birth-rate, a high death-rate was to have been expected, seeing that the mortality amongst children in their first year of life is nearly always far higher than amongst an equal number of persons during any subsequent year of life. The higher the proportion, therefore, which the portion of the population in the first year of life bears to the total population, the higher will be the death-rate. In other words, under ordinary conditions, the higher the birth-rate the higher will be the death-rate. It is quite certain that the recorded death-rate amongst infants under one year of age, which the Sanitary Commissioner regards as indicating an "extraordinarily great" loss of life, is very far from representing the entire loss. During the year under review the death-rate per 1,000 of children born is recorded to have been 186·39. As the Chief Commissioner points out, these figures, instead of being considered to be remarkably high, should rather be characterised as low. In Goalpara, the district in the Brahmaputra Valley in which registration of vital statistics is acknowledged to be the most efficiently carried out, the recorded death-rate amongst infants under one year of age was 296·46. In no other district of this region did the rate reach 200 per 1,000 of the children born, and in one of them it was only 96·32. "The truth is," as the Chief Commissioner writes, "that infant mortality in India is much higher than is commonly supposed, and it is principally under the head of infant mortality that registration is defective." In the districts in which it is effected through paid village watchmen, registration has greatly improved. Strenuous efforts are made to see that the watchmen do not neglect this part of their duties. No fewer than 830 of the paid staff of watchmen were punished for neglect to report births or deaths in the three districts of Sylhet, Cachar, and Goalpara; whilst in the rest of the districts of the Province, where unpaid agents known as *gaonburas*, are employed, only 34 were punished for such neglect. It may be difficult, or inexpedient, to punish men for the neglect of duties for the performance of which they receive no remuneration. However this may be, the results obtained in the two classes of agents are widely different. Where paid watchmen are employed to collect vital statistics, and are strictly supervised, the work is comparatively well done; where unpaid *gaonburas*, or village headmen, who probably cannot be strictly supervised, are employed, the work is badly done. The registration question in Assam, as elsewhere, is no doubt mainly a financial one.

5. *General History of Chief Diseases.*—The mortality from *cholera*, which had decreased from 33,754 deaths in 1897 to 11,288 in 1898, further fell to 8,380 in the year under report, and was less than half the average for the ten-year period 1887–96. In the very full account given by the Sanitary Commissioner of the history of the disease for the year, allusion is repeatedly made to the connection between outbreaks in different parts of the Province, and the batches of immigrant coolies who mostly came up by river to work on tea gardens. In the first paragraph dealing with cholera it is stated:—"There was a slight outbreak in both valleys in November and December, owing chiefly to deaths amongst immigrant coolies, otherwise the disease might almost have been called non-existent." Regarding the outbreak in the Goalpara district, "it apparently originated in the river-side depôts amongst batches of infected tea garden coolies, who then spread it about." In the Darrang and Sibsagar districts the tea-garden coolies suffered most. Of Lakhimpur it is stated: "There was practically no cholera in the district, but the tea gardens reported 212 cases, which brought the district rate up to 1·00; were these omitted the rate would be 0·017 only." And, finally, we read in paragraph 44:—"The incidence of the disease on tea gardens is always more severe than elsewhere; in fact, epidemics frequently start from them, and as most batches of coolies coming up by steamer or rail are infected, it is no wonder the managers cannot keep their estates clear." It might be gathered from these remarks that if the stream of coolies, which flows annually into the Province, were cut off, cholera would largely disappear. Unfortunately, no reliable statistics are available from which any conclusions can be drawn regarding the comparative prevalence of cholera in Assam before and after the opening out of tea gardens, which led to the introduction of coolies from

inces. But there is evidence that the disease is not always imported by immigrants. In up district cholera is stated to have been "endemic" in some circles throughout the year. gard to the river-side population of this district the Sanitary Commissioner writes:— ms impossible to keep the river-side population from drinking the water in dirty and d back-waters and semi-stagnant rivers, and so I suppose the disease will always be present it may vary in activity from time to time." From this statement it may be assumed s the disease prevails endemically in the Province, outbreaks may occur which cannot be l to the introduction of infection by immigrant coolies. Moreover, it is doubtless the case that, st, owing to the more thorough supervision to which they are subjected, tea-garden coolies rarely ever suffer from cholera without the fact being reported and a record made of the resulting ortality, cases of the disease may occur among the general population of the Province and escape otice. The table given in paragraph 7 of the review of the Report by the Chief Commissioner, hows that only 72 cholera deaths occurred during the year on "steamers and at depôts among coolies oming up the Brahmaphutra Valley." Regarding the recrudescence of the disease at the close of the ear, which, as already noted, the Sanitary Commissioner attributes chiefly to deaths among mmigrant coolies, the Chief Commissioner says:—"This did not occur among immigrant coolies, as s incorrectly stated in the Report." Importation of infection seems so simple an explanation of utbreaks, that there may occasionally be some risk of exaggerated importance being assigned to it nd of local causes being overlooked.

6. *Small-pox* was less fatal than it was in either of the two preceding years, and the death-rate of 0·31 attributed to the disease was lower than the average for the ten years 1887–96. The single district of Darrang contributed by far the greater number of the small-pox deaths which occurred in the Province during the year under report. This district is contiguous with that of Nowgong, which suffered from a violent small-pox epidemic in the previous year, and from which the disease may have spread into Darrang. The Sanitary Commissioner writes of "the terrible epidemic in Nowgong during 1898 having been quite stamped out." But perhaps it would have been more correct to have described it as having burnt itself out. In this district owing to their bigoted objection to vaccination, the inhabitants are very insufficiently protected against small-pox; and the epidemic just ended would not seem to have led to an increase, but rather to a decrease in the number of persons who underwent vaccination. During 1897–98 the number vaccinated in the Nowgong district was 19,630; next year, when a destructive epidemic of small-pox prevailed, the numbers fell to 9,347 or to less than half; whilst in the year under report they were still as low as 10,259. The vaccination staff of the Province was practically of the same strength as in the previous year. The number of vaccine operations performed by all agencies increased from 258,905 in the previous year to 272,265 in the year under report. The percentage of success in primary vaccination was 98·50, or almost the same as in the previous year; whilst in re-vaccination it fell from 93·78 to 88·90. "As the primary work becomes more and more thorough," writes the Sanitary Commissioner, "re-vaccinations will tend to show a smaller percentage of success." To some extent this may be true; but the difference in the quality of the primary vaccination in different provinces would not account for the return, for example, of a percentage of less than 20 in Calcutta and less than 30 in Berar; whilst Assam, the Central Provinces and Madras return percentages of from 80 to 90. These wide differences are probably to be explained rather by assuming that the standard by which cases of re-vaccination are decided to be successful or unsuccessful is not everywhere the same. A satisfactory feature of the season's work is the increase in the number of children under one year of age who were vaccinated. In the previous year this number was 50,389; in the year under report it was 61,793. It will be noted, however, that even the latter figures fall very far short of the number of births registered during 1899. After deducting the deaths of children under one year of age from the number of registered births, there would still remain available for vaccination 145,647. A good many of those would probably not be in a fit state to be vaccinated; but even when full allowance has been made for these, at least half the number of infants under one year would remain unvaccinated. The quality of the vaccine lymph supplied from the depôt at Shillong continued to be excellent. Colonel Campbell, the Civil Surgeon, appears to have successfully overcome the difficulties which other Medical Officers in India have hitherto found to be insurmountable in their endeavours to preserve unimpaired the activity of calf lymph by mixing it with glycerine. Prepared by Colonel Campbell's method, lymph which had been kept in the depôt for over six months for experimental purposes "was as efficacious as at the time of manufacture." In an interesting account given of his experiments Colonel Campbell describes his method of vaccine lymph preservation. It seems to be simple; and unless the climate of Assam is specially favourable to its success, and the climates of other provinces unfavourable, there appears to be no reason why his method should not be adopted throughout India. Colonel Campbell writes:—"Two thousand tubes manufactured on the 11th February and 15th February 1900 were forwarded to the Principal Medical Officer and Sanitary Commissioner, Assam, to be kept for experiment next season. This will be an interesting experiment to see if lymph will keep in the plains through a hot weather if not exposed to sunlight or heat, *i.e.*, if simply shut up in a wooden box. I believe this will prove to be the case."

7. The mortality from *fever*, including that description of it known as *kala-azar*, has greatly diminished during the past two years, but is still higher than the average for the decade 1887–96. In the year under report the death-rate from this cause was 18·04 per 1,000 of population, as compared with 20·95 in the previous year, and with 28·72 in 1897. Of the total recorded number of 91,096 fever deaths in the Province, 14,246 are differentiated as *kala-azar*. In three districts only was this form of fever reported to be very prevalent; and in these it is probable that many cases of ordinary malarial fever have been included in the returns as *kala-azar*. "There is a natural tendency in tracts where *kala-azar* prevails to class all deaths from fever under that head, and no reliance can be placed on local diagnosis." This tendency to mix up in the returns *kala-azar* and ordinary malarial fever need not be wondered at, seeing the close relationship which the weight of expert opinion appears to have established between them. Of a total of 9,111 deaths from fever in the Nowgong district, all except 919 are ascribed to *kala-azar*. Of *kala-azar* the Sanitary

Commissioner writes :—"On the whole the epidemic may be said to be surely, if slowly, ce[illegible] whether it will disappear without infecting the Sibsagar and Lakhimpur districts is m[illegible] anyone can predict." With diminished fever prevalence the sales of quinine fell off; on[illegible] packets having been sold, as compared with 3,750 in the preceding year.

8. *Sanitary Works.*—Although no sanitary works of magnitude were undertaken during th[illegible] the list of useful minor sanitary improvements carried out in municipalities, unions, station[illegible] towns is a long one. Attention was more especially devoted to the improvement of the [illegible] supplies and to clearing out the repairing drains. The question of the disposal of night-soil o[illegible] special difficulties in Assam. When suitable ground is available near towns the *trenching* system probably the best. But the people obstinately refuse to cultivate land in which night-soil has bee[illegible] trenched. Under these circumstances the Sanitary Commissioner suggests the employment [illegible] incinerators for burning night-soil. But to this, likewise, the municipalities strenuously object owing to the difficulty of overcoming the unpleasant odours given off when such refuse is being burned. Village sanitary improvement is mainly confined to the construction and repair of wells and the excavation and deepening of tanks. There is probably no way in which the limited funds available for rural sanitation could be laid out to better advantage. Village sanitary inspection books were maintained in selected villages and submitted to Civil Surgeons with more or less of irregularity during the year. Some of the Civil Surgeons do not regard the entries in these books as being of much practical value.

9. *Summary.*—The year was a comparatively healthy one. It was exceptionally cool. Harvests were good and food cheap. The birth-rate, which during the two preceding years had been lower than the death-rate, exceeded the latter by 4·45 per 1,000 of population. Deaths from cholera decreased from 33,754 in 1897 to 11,288 in 1898; and now in the year under report to 8,380. The Sanitary Commissioner traces a connection between outbreaks of the disease and the arrival in the Province of batches of coolies recruited in other provinces for employment in the Assam tea gardens. Small-pox was less fatal than in either of the two preceding years. Vaccination made good progress, and a satisfactory feature of the season's work was a substantial increase in the number of children under one year of age who were vaccinated. The quality of the vaccine lymph sent out from the Shillong depôt was excellent, and the percentage of successful cases following its use was high. Colonel Campbell, the chief Surgeon of Shillong, appears to have succeeded in preparing a mixture of vaccine lymph with glycerine and water which retains its activity for months. Fever was much less prevalent and fatal than in either of the two previous years. The form of it described under the name of *kala-azar* is believed by the Sanitary Commissioner to be slowly but surely ceasing in the Province. He adds, however, that, whether it may extend to Sibsagar and Lakhimpur districts, no one can predict. No sanitary works of magnitude were undertaken during the year; but much attention was devoted to the improvement of water-supplies and drainage in municipalities. Rural sanitation was promoted to the extent to which the funds available permitted.

No. 8.

Memorandum by the Army Sanitary Commissioner on the Medical and Sanitary Report of Coorg for 1899.

The health of this small Province was better than it had been during either of the two preceding years. The rainfall was less than usual: only 91·12 inches of rain was measured as compared with 122·67, the mean of the previous five years. The mean temperature of the year was 68·5; and the maximum on any one day did not exceed 88·50. The staple food grains were somewhat, though not much, cheaper than in the two preceding years; but they are still very much dearer, especially *raggi* and *gram*, than in the years preceding 1897. In 1896, 25 seers of *raggi* could be got for a rupee; and in the year under report only 19·7. The price of common rice appears to vary little from year to year.

2. The recorded number of *births* increased from a total of 2,795 in the previous year to 4,427 in the year under review; and the birth-rate from 16·15 to 25·59 per thousand of population. The peculiar constitution of the population of Coorg results in an abnormally low birth-rate being annually recorded. Of the total population, numbering according to last census 173,055 persons, about 50,000, or more than a fourth, are immigrant coolies who come to work on the coffee estates for six or seven months of each year. As these coolies are rarely accompanied by their wives, they contribute little or nothing towards the birth-rate; whilst they form more than a fourth part of the population on which the birth-rate of each year is calculated. As they do not contribute to the births of the year, their numbers should be deducted from the population figures on which the birth-rate is calculated. If this is done, the abnormally low birth-rates hitherto recorded in Coorg would disappear, and give place to rates more in harmony with those prevailing in other provinces. If the 50,000 immigrant coolies are deducted from the census population figures, Colonel Bain shows that the birth-rate of only 25·59 recorded for the year under report becomes 35·97. But even when the birth-rate has thus been brought more into line with that elsewhere recorded, some peculiarities remain unexplained. In other provinces the percentage of male children is in excess of the percentage of female children born. In Coorg the reverse is the case: the percentage of female exceeds the

of male births. In the year under report, for every 100 female children born only 95·8 e born. In the Madras Presidency the proportion was 103·9 male to every 100 female born.

Whilst the number of births increased, the number of deaths decreased. The death-rate for the ious year was 31·44, and in the year under report 28·00. The increased mortality amongst ren under one year of age is a noticeable feature of the returns for the year. In the previous 742 children of less than a year of age died : in the year under report the number rose to 1,024 ; yet the latter was the healthier year. The death-rate amongst male children under one year of ose from 187·02 per thousand living in 1898 to 251·42 in 1899 ; and amongst female children of same age, from 157·08 to 223·18. Possibly, the explanation of this greater mortality amongst ants during the healthier year of 1899 may be due to improved registration of births. "Excluding ants," writes Colonel Bain, "3,161 deaths out of a total of 4,845 for the Province occurred between e ages of 20 to 50, which represents the working period of life, and this again shows that the large ortality is due to the influx of coolies." The Chief Commissioner has directed that the deaths mong the immigrant coolies shall be registered separately from those among the indigenous opulation of the Province. The figures for 1900 tabulated under the new system cannot fail, he hinks, to be instructive.

4. *Chief Diseases.—Cholera* was entirely absent from the Province. *Small-pox* accounted for 28 eaths : this would give a ratio of 0·16 per thousand of population. Since the severe small-pox pidemic of the years 1891-93, the death-rate from this disease has in no year reached 1 per thousand f the population. Vaccination, the progress of which had been greatly retarded during the previous ear by the plague-inoculation scare, recovered most of the ground then lost. The total number of ersons vaccinated and re-vaccinated by all agencies during the year under report was 10,477, as ompared with 5,673 in the year 1898-99. The figures for the year 1897-98 were, however, higher han those for the year under report by 500. In all vaccination operations calf lymph alone was used. The percentage of success obtained by the regular establishment was 94·93 in primary vaccination, nd 76·48 in re-vaccination. The percentage of success recorded in the 481 cases vaccinated at the lispensaries was only 75·40 in primary vaccinations, and 55·23 in re-vaccinations. Of the total population of the Province, 54·69 were protected by vaccination, as compared with only 29·46 in the previous year. According to Vaccine Statement A in the Appendix to the Report, the number of children under one year of age who were successfully vaccinated was only 800. The great majority, 4,825, of those who were successfully vaccinated, were over one year and under six years of age. These numbers are exclusive of dispensary vaccination cases.

5. Under the head of *Fever*, the greater part of the mortality of the year was, as is usual, recorded. The death-rate attributed to this cause was 23·10 of a total of 28 per thousand from all causes. Doubtless, in Coorg as in other provinces, deaths from a variety of other diseases are entered under the head of fever. As compared with the fever death-rates recorded for the previous two years, the rate for the year under report shows a marked decrease. In 1897 the death-rate from this cause was 41·50, in the year following 27·02, and now 23·10. This lessened fever mortality probably bore some relation to the diminished rainfall of the year. A similar connection probably existed between a drier season and a marked decrease in the mortality from *diarrhœa and dysentery*. The death-rate attributed to these two diseases was 0·64 per thousand of population, against a mean of 1·85 for the previous five years. The Province "providentially escaped the plague, although it crept up almost to the frontier on the Mysore side."

6. The sections of the Report dealing with jails, dispensaries, and sanitary works, need little notice. The health of the prison population is described as having been "good" ; but this does not seem quite consistent with the figures given in Statement No. XIV. of the Appendix. From those figures it appears that, out of an average daily strength of 110·49 prisoners of all classes, 14 died during the year, giving a death-rate per thousand of strength of 126·71. As might have been expected, the attendance at the dispensaries fell off during so healthy a year ; the total number of patients treated having decreased from 41,396 in the previous year to 33,753 in the year under review. The number of surgical operations fell at the same time to 473. Some useful sanitary works were carried out during the year. Doubtless the funds available for such works were much reduced by the cost of the arrangements which were considered necessary for the defence of the Province against threatened invasion by plague.

7. *Summary.*—The sanitary history of the year was uneventful. The health of the population was better than it had been in either of the two preceding years. A disturbing element in the vital statistics of Coorg is the immigrant coolie section of the population. These coolies, who annually enter the Province and remain on the coffee estates for six or seven months, do not bring their families with them, and do not, therefore, contribute to the birth-rate, whilst they add largely to the death-rate. The result is the annual record of an abnormally low birth-rate and of a high death-rate. The Chief Commissioner has directed that in future the deaths amongst these immigant coolies shall be registered separately from those occurring amongst the indigenous population. The birth-rate recorded for the year was 25·59 ; but if the 50,000 immigrant coolies are deducted from the population numbers when calculating the birth-rate, the result would be 35·97 instead of 25·59. The death-rate fell from 31·44 per thousand of population in the previous year to 28·00. The decrease was doubtless due, in part, to the fact that the year was drier, and probably, therefore, healthier than either of its two predecessors. The decrease in the number of immigrant coolies employed on the coffee estates during the last six months of the year, owing to the depressed state of the coffee industry, likewise contributed to lessened mortality. Cholera was entirely absent throughout the year ; and small-pox accounted for only 28 deaths. Vaccination made satisfactory progress, recovering most of the ground lost in consequence of the unfortunate plague-inoculation panic, which had brought operations to a standstill for some months of the previous vaccination year. Fever and bowel-complaints were less fatal than usual, a result which may, perhaps, be credited to the exceptional dryness of the year. Plague was

successfully excluded from the Province, notwithstanding that it closely approached [illegible]. The health of the prisoners is said to have been good; although the jail mortality ret[illegible] hardly consistent with this statement. As was to be expected in so healthy a year, t[illegible] dimished attendance at the dispensaries. The number of surgical operations likewise considerably.

14th May, 1901.

No. 9.

Memorandum by the Army Sanitary Commission on the Rajputana Sanitary, Vaccination, Dispensary and Jail Report for 1899.

Along with the Report itself, the Army Sanitary Commission have been favoured with a copy of a note on it by the Director-General, Indian Medical Service. In this note the importance of registration as constituting "the fundamental basis of all fruitful sanitary effort" is insisted on, and the need for its improvement, more especially in the Native States, shown to be urgent. Further, the relation demonstrated by recent research to exist between malarial fevers and mosquitos is discussed and medical officers and subordinates enjoined to aid in the collection of information regarding the distribution in time and place of the varieties of mosquitos concerned in the propagation of fever. The note ends with a brief commentary on the progress of vaccination in Rajputana. The Director-General's review embraces the chief points dealt with in the Report, and any additional remarks which the Army Sanitary Commission may have to make need, therefore, only be of the briefest.

2. The year under report was, like its predecessor, one of deficient rainfall. At Ajmer only 1[illegible] inches of rain were registered, or less than half the average fall for the previous six years; and in Bewar only 5·10, against an average of 22·75. In the Western States of Rajputana and Bikaner there was no rain worth mentioning. In consequence of this failure of the rainfall, the crops withered, and the tanks and wells dried up. Under the influence of abnormally high prices of grain and scarcity of good drinking water, the death-rate, which in Ajmer-Merwara had been 22·13 in the previous year, rose to 33·21 in the year under report, per thousand of population.

3. In our memorandum for 1898 that year was described as having been a "comparatively healthy" one. The *birth-rate* of 1899, influenced as it of course was mainly by the conditions which prevailed during the preceding comparatively healthy year, rose from 29·73 per thousand of population in 1898 to 31·40; but this was still below that recorded for 1897, when it was 33·69. It is pointed out in the review of the Report by the Agent to the Governor-General that there is a remarkable difference between the birth-rate recorded for Ajmer and that for Merwara. In the former it was only 29·39 and in the latter 38·4. This wide difference is attributed to the unsatisfactory condition of registration in the Division.

4. The marked increase of the *death-rate* in Ajmer-Merwara from 22·13 in the preceding year, to 33·21 in the year under review, is attributed by the Administrative Medical Officer to deaths among people who had immigrated on account of famine from the neighbouring Native States. All of the principal diseases were more fatal than in the previous year. Cholera was, however, practically absent from Ajmer-Merwara, only three cases with one death having been attributed to it, as compared with no deaths in 1898. But in five Native States there were 846 cases, and 497 deaths from cholera, as compared with only six cases and six deaths in the previous year. Small-pox deaths more than doubled in number, as did also the deaths from diarrhœa and dysentery. Mortality from bowel complaints was doubtless increased by the scarcity of good drinking water, and the insufficiency or unsuitableness of the food available during a season of distress. Regarding the water supply of Ajmer city, the Administrative Medical Officer says that the lake from which this is obtained dried up altogether owing to the scanty rainfall for two successive years; but he adds that the discomforts of a water famine were averted by the introduction by pipes of a supply from another lake. "The water of both lakes," he remarks, "has been condemned by the Chemical Examiner, but it is excellent nevertheless."

5. That *Sanitation* is receiving attention in Rajputana is made clear by the detailed account given of its progress in all the important States. "Protection of the water-supply, regular cleansing of cities and towns, and surface drainage, are receiving much more attention than hitherto." Village sanitation is not overlooked; but until the rural population is better educated than at present, much permanent improvement in the sanitary condition of their villages can scarcely be looked for.

6. The numbers *vaccinated* during the year show a considerable increase over those for the previous year; but in some of the Native States little is yet being done, it is said, to mitigate the ravages of small-pox. Humanised vaccine lymph is still generally used, although buffalo calf lymph, it is stated, was used as much as possible. This year, again, the percentage of successful cases in certain Native States is phenomenally high. In five of these States all of the cases of primary vaccination were successful. In Kotah the primary vaccinations numbered 24,244, and every one of these, according to Annual Statement I., proved successful. Yet, to quote from the Report, "the inspection of vaccination work during the year received vigilant attention from the various Agency Medical Officers."

7. The *dispensaries* at the close of the year under review numbered 165, as compared with 157 at the end of the previous year. The number of indoor patients nearly doubled, and that of outdoor patients showed a considerable increase. As usual, malarial fevers and spleen diseases were the most

ments treated. There was, however, a marked decrease in the number of admissions rial fevers, due, no doubt, to the unusual dryness of the year, consequent upon the failure of On the other hand, "the deaths from diarrhœa and dysentery were more numerous than evious year, and these diseases would naturally be more fatal among a population reduced erior food and scarcity than a year of plenty." The water famine following the failure of the doubtless contributed to the increased prevalence and fatality of bowel complaints. The sale nine diminished by half, and this is attributed to lessened prevalence of malarial fevers; but npoverished condition of the people during a year of scarcity and high prices may also have ts share in diminishing the sales of quinine by lessening the ability of the people to purchase it. ast amount of surgical work was done; the number of operations increased both in the Ajmer-wara Division and in the Native States. In the former these rose from 3,019 in the previous r to 3,197, and in the Native States hospitals and dispensaries from 61,470 to 62,213. The preva-ce of leprosy in Rajputana continues to diminish. "No cases of indigenous bubonic plague urred in Rajputana during the year 1899."

3. Owing to the prevalence of famine, crime increased, and the average number of prisoners in the l at Ajmer, and in the twenty jails in Native States rose, in the case of the former from 287·74 in e previous year, to 371·70; and in the case of the latter from 4,679·58 to 5,194·51. The death-rate the Ajmer jail remained at nearly the same level as in 1898, showing, however, a slight decrease; it in the jails of the Native States the death-rate, which had been only 19·23 in the previous year, se to 29·84 per thousand prisoners. Under the conditions of famine and water scarcity which aracterised the year, the only wonder is that the death-rate did not largely exceed the latter figures. f the deaths in the jails of the Native States 35 per cent. were due to dysentery and diarrhœa. he Administrative Medical Officer attributes the increased death-rate in these jails "partly to over-owding and partly to the weak state of health of many of the prisoners on admission." It is tisfactory to learn that the construction of new jails in Banswara and Pertabgarh on healthy sites under contemplation. The high death-rate recorded in the former of these jails has hitherto epeatedly attracted attention.

9. *Summary.*—Accompanying the Report there is a note by the Director-General, Indian Medical Service, briefly reviewing it. The failure of the rainfall, which was also a marked feature of the previous year, recurred in a more aggravated form during 1899. Not only did grain crops and fodder for cattle wither, but the lakes and wells dried up. The birth-rate, influenced mainly by the comparative healthiness of the previous year, showed some increase. It was only to be expected that scarcity of food and good water should have the effect of raising the death-rate. Sanitation continues to receive attention both in towns and villages; but progress is not likely to be rapid until the return of more prosperous times. The numbers vaccinated show a decided increase. The same phenomenally high percentages of successful cases hitherto recorded in Native States continue to be a striking feature of the vaccination returns. Famine brought with it, as usual, increase of crime and a more crowded state of the jails. The death-rate amongst the prisoners as a whole was not, however, excessive. It is satisfactory to note that some of the more unhealthy of the jails in Native States are to be replaced by new ones.

5th July, 1901.

No. 10.

MEMORANDUM by the ARMY SANITARY COMMISSION on the REPORT of the SANITARY COMMISSIONER of MADRAS for 1899.

As in the previous year, the Report of the Sanitary Commissioner is submitted to the Government of the Presidency by the Sanitary Board, together with the Board's own Report and the Report of the Sanitary Engineer. In the same volume are thus included three reports, each of which receives a separate notice in the Government review. The Sanitary Board, one of the chief functions of which is to consider the various sanitary schemes submitted to it, and to advise and decide as to their fitness for being put into execution, scrutinised during the year under report plans and estimates of 114 sanitary works of the total estimated value of nearly 20 lakhs of rupees. The Board does not confine itself to an examination in the Board-room of the plans and estimates laid before it: when considered expedient its members assemble on the site of the proposed works and form their opinions regarding them, from observations made on the spot. On at least two occasions, the latter procedure was followed during the year. As might have been expected, the Board's Type Designs of buildings are found of use beyond the limits of the Madras Presidency. "Many of them," it is stated, "have been found too expensive for the minor bodies of the Presidency, and the Sanitary Board is now arranging for the preparation of cheaper designs for various buildings."

2. From a meteorological point of view, the most important feature of the year was its rainfall. Compared with an average of 45·72 inches for the 10 years ending 1896, the rainfall recorded during the year under review was only 21·92 inches, or less than half for the Presidency as a whole. The effect of this deficient rainfall upon the prices of food grains was not marked until the last quarter of the year, when the failure of the north-east monsoon made it certain that this would be followed by a bad harvest. The table given on page 23 of the Report shows that in two selected districts, the staple grains, taking their average price for the whole year, were much cheaper than in either of the two preceding years. In the last three months, however, with the prospect of crop failure and with

grain being bought up for other provinces overtaken by scarcity or famine, prices What of adverse influence this rise in the price of food during the last three months of th have exercised on the public health, was probably more than counterbalanced by the unusu succeeding to failure of the north-east monsoon. As judged by its death-rate, the year was le than its predecessor.

3. *Registration* of births and deaths, hitherto, and still, a weak feature of the vital statistics Madras Presidency, is receiving ever increasing attention. The introduction of the "Madras Reg tion of Births and Deaths Act" of 1899 may be expected to hasten improvement. One of obstacles in the way of the successful working of this Act is said to be the difficulty in findin sufficiently educated staff to undertake the duties of registrars. As the Sanitary Commissioner s the creation of a specially organised staff "would create financial difficulties, not likely to be ov come." According to the last census figures, the population of the Presidency exceeds thirty-f and a half millions; but for upwards of two millions of these, no vital statistics are yet collect By degrees, however, registration of births and deaths is being extended to the entire populati The Sanitary Commissioner illustrates by examples the ill effects of undue leniency in the admini tration of the rules for obliging the inhabitants of municipalities to register births and deaths. I most of the sixty municipal towns of the Presidency penalties were inflicted for breach of the rules; but in a few, the record of prosecutions for failure to carry out the rules is blank, and i these latter poor registration results are usually obtained.

4. In the Madras Presidency, as in some of the other Indian Provinces, the *birth-rate* for 1899 w the highest on record. From a ratio of 24·6 per 1,000 of population, in the previous year, it rose t 31·3 in the year under review. This increase in the birth-rate was probably due to a combination causes. A table is given showing that, excepting in 1896 and 1897, when the number of birth decreased in sympathy with the prevailing conditions of scarcity or famine, there has been a steady increase in the birth-rates registered from 25·1 in 1892 to 31·3 in the year under report. This increas the Sanitary Commissioner attributes "to better attention to registration by all concerned." It is also shown that the increase of population since last census has necessarily tended to raise the recorded above the actual birth-rate. If the birth-rate is got by using, in calculating it, the lesser population numbers of last census, instead of the greater population numbers of the year yielding the births, it is obvious that the real rate will not be obtained. The exact population numbers of the year under report are not obtainable; but taking the estimated numbers and calculating therefrom the birth-rate, it will be found that this is considerably less than the recorded rate. Using the census population figures, the birth-rate for the year works out to 31·3; and using the estimated population figures to only 27·4 per 1,000. In addition to these two causes which tended to raise the birth-rate, there was yet another. In the Madras Presidency, as in other Provinces in which the population underwent distress from scarcity of food, the depression of the birth-rate following, and doubtless chiefly, if not entirely, due to this distress, was succeeded by reaction. The return of prosperity in succession to a period of distress was followed in due course by a remarkable increase in the number of children born. Some part of the decreased fecundity in hard times may perhaps be explained by assuming that marriages are then postponed until the return of prosperity. And, similarly, some part of the increased fecundity of a period of prosperity succeeding a period of distress may be ascribed to the taking place of marriages which had been postponed until the season of distress had passed. But to whatever cause, or causes, it is due, reaction from an abnormally low to an abnormally high birth-rate seems ordinarily to characterise a season of prosperity succeeding a season of scarcity.

5. The total number of deaths gives a ratio of 20·1 per *mille* on the census population, as compared with a ratio of 21·0 for the previous year. In other provinces an increase in the birth-rate has almost constantly been accompanied by an increase in the death-rate; but such has not been the case in the Madras Presidency during the year under report. The birth-rate has risen from a ratio, per thousand of population, of 24·6 in 1898 to 31·3 in 1899; and at the same time the death-rate has decreased from 21·0 in the former year to 20·1 in the latter. The following comment by the Sanitary Commissioner on the causes of the defective record of deaths seems to throw light on this failure of the death-rate to increase in unison with increase of the birth-rate. "One cause of deficient death-rate is certainly a tendency to ignore the deaths of infants below one year of age. This conclusion was forced upon me by the persual of numerous abstracts of village registers furnished to this Office by District Medical and Sanitary Officers during their inspections. It was obvious that the death of an infant who had not managed to struggle through a year of life was often held unworthy of official recognition, with the result of marring the total statistics supplied." Examining the table given in paragraph 18 of the Report, it is seen that the general infantile death-rate for the Presidency was only 159·0 per *mille* of births: in one district it is as low as 96·7. There can be no doubt that in the municipality of Madras itself the registration of vital statistics is effected with a nearer approach to accuracy than has been yet attained in any of the districts in the Presidency. The recorded death-rate amongst children under one year of age in the city of Madras for the year under report was 275·6 per 1,000 of births. As already noted, the general provincial death-rate recorded for children under one year of age was 159·0. These figures would appear to confirm the Sanitary Commissioner's conclusion that one cause of the lowness of the death-rate in the Presidency is failure to register the births of infants. The registration of births and deaths in the municipalities of the Presidency is acknowledged to be more accurate than their registration in rural circles. The birth-rate in the municipalities during the year under review rose from 34·9 in the former year to 37·0, or by 2·1: at the same time the death-rate fell from a ratio of 31·9 to a ratio of 30·7, or by 1·2. Seeing that the recorded death-rate of infants in municipalities was 233·9, it is evident that if the increase in the birth-rate had been great instead of, as it was, only inconsiderable, the death-rate would also have been proportionately higher. In Madras city itself, the vital statistics of which may be assumed to be the most accurate available in the Presidency, the birth-rate of the year under review was 40·4 as compared with 41·5 the previous year. Accompanying this decrease of the birth-rate the death-rate decreased from 45·2 to 38·5 per *mille* of population.

History of Chief Diseases.—The number of deaths from *cholera* was less than half that [illegible] the previous year, the death-rate falling to 0·9 from 2·0 per 1,000 of population. "As [illegible]inted out in former reports, the incidence of mortality was, as usual, in the south-west [illegible] districts greatest during the south-west monsoon, and, in the north-east monsoon districts, [illegible] north-east monsoon." The Sanitary Commissioner says that all the evidence received [illegible]es to point to the usually accepted fact that water contaminated with the specific germ is the [illegible]ethod of local propagation of the disease. Medical officers continue to report favourably upon [illegible]se of permanganate of potassium "in specifically contaminated water sources," but point out [illegible] this mode of disinfection often results in the use by the people of water from other sources. [illegible] definite statements can, under such circumstances, they admit, be made regarding the efficiency [illegible]ermanganate as a disinfectant.

. Small-pox mortality has again decreased. In 1897 the recorded death-rate from this disease [illegible]s 0·7 ; in the following year 0·6 : and now, in the year under report, 0.5 per 1,000 of population. [illegible]ccination made good progress, regaining much of the ground it had lost in the previous year, [illegible]owing to a scare consequent upon the people having hopelessly confused the operation of inoculation against plague with that against small-pox. An opinion existed, writes the Sanitary Commissioner, that plague was being spread among the people by inoculation under the guise of vaccination. This [illegible]are has fortunately subsided ; and although the number of successful primary vaccinations is still [illegible]ehind the number for 1897–98, it exceeds that of 1898–99 by 73,783 cases. The number of [illegible]e-vaccinations, on the other hand, shows a decrease of 15,692 cases. In the seven districts which [illegible]ecord a decrease in the amount of work during the year, this decrease is attributed in most of them [illegible]o absence of vaccinators from their posts, without substitutes having been appointed to take their [illegible]laces ; to continuance of the plague scare, and to the subsidence of small-pox disease. In both [illegible]rimary vaccination and re-vaccination the percentage of successful cases shows a substantial increase ; [illegible]n the former from 89·5 to 91·8, and in the latter from 75·4 to 76·1. The variations in the percentages of success in re-vaccination recorded in different provinces has often been noted : they are probably [illegible]hiefly due to differences of opinion as to the line which should separate successful cases from [illegible]ailures. In Germany, as we have noted in another *memorandum*, the percentage of success recorded in re-vaccination was 91·59 in the year 1898. A satisfactory feature of the season's work as compared with that of the previous year, is the marked increase in the number of young children vaccinated. The table given in paragraph 8 of the Vaccination Report, shows clearly the progress of infantile vaccination in rural and municipal Madras. In the districts, exclusive of municipalities, the proportion per cent. of the children born who were vaccinated was 25·8, in municipalities it was 79·2. In the large district of Malabar the percentage recorded was only 1·2. The results given by the different kinds of vaccine lymph used in primary vaccination during the year do not seem to differ greatly from those hitherto recorded. As usual, calf-to-arm vaccination has given the highest percentage of successful cases. Last year this percentage was 97·2, and in the present year 97·3. Next in efficiency comes calf lymph stored in glass without any admixture ; this gave a percentage of 95·7 successful cases. The efficiency of vaccine lymph thus preserved would ordinarily vary inversely with the length of time elapsing between the taking of the lymph from the calf and its subsequent use for vaccinating. After this, but at a long interval, follows lymph mixed with glycerine as a preservative. From the use of this paste a percentage of 88·9 successful cases is recorded. Last of all comes lanoline paste, with the slightly lower percentage of 88·4. The conclusion arrived at regarding the use of glycerine as a preservative of vaccine lymph is pretty much the same as that reached in some other provinces of India. The Inspector-General states "that glycerine paste gives results which approximate to those of animal lymph if used at once, or almost at once, but which are inferior in proportion to the amount of delay that may occur, and that it is therefore incapable of prolonged retention of activity—possibly a matter of minor importance in a temperate climate, but of special importance in the tropics." The results recorded by medical subordinates are at variance with those obtained by the vaccination establishment. In the hands of dispenary staffs and medical subordinates glycerine paste gave better results than lymph taken direct from the calf, the former giving a percentage of 84·1 as compared with only 77·9 given by the latter. Similar unexpected results obtained by the same class of operators were recorded in the previous year.

8. The mortality from *fever* was the lowest recorded since 1883. The death-rate from this cause was only 7·3 per 1,000 of the population. To the exceptional dryness of the year, and "to the not insignificant desire on the part of those registering deaths to escape the suspicion of a disease whose prominent symptom is fever, namely plague, rather than to drainage on a scale large enough to have much effect in reducing moisture in the soil, or the abundance of mosquito life thereupon depending," the Sanitary Commissioner attributes the diminished fever prevalence of the year.

9. The mortality from *diarrhœa* and *dysentery* was the same as during the previous year. Judging from the death-rates recorded in municipalities as compared with those in rural area, these diseases are vastly more fatal in the former than in the latter. In municipalities a death-rate of 4·3 per 1,000 of population is attributed to them, as against a rate of only 0·7 in rural areas. But registration of deaths is so much better carried out in the former than in the latter that it would hardly be safe to accept these figures as correctly representing the comparative fatality of these diseases in town and country.

10. The total attacks of *plague* in the Presidency during the year numbered 2,385 ; and of these 1,843 proved fatal. To some, these figures will doubtless appear insignificant in proportion to the excitement and anxiety caused by the disease, or the elaborate and costly measures taken with a view to staying its progress. But, looked at from another point of view, they may be taken as a proof of the success of those measures. The Sanitary Commissioner when describing the system of dealing with plague which has been followed in Madras, says, "the amount of success which has attended the endeavour suffices to prove its great utility, more especially when contrasted with the inconvenience and indifferent results in at least one other Presidency, by the adoption for a considerable

period of the principle of 'detention camps and quarantine.'" With the view of demand of certificated Sanitary Inspectors for plague duty, the Sanitary Commissione class of candidates for instruction in practical hygiene. "The endeavour was to train we men so as to be capable of recognising the disease, of taking necessary preliminary acti understanding the methods and reasons for disinfection." Nothing is more likely to conduc success of plague measures, some of them requiring delicate handling, than the provision of a well-educated, trained and tactful men to carry them into effect.

11. *Sanitary Works.*—In the year under report no sanitary work of great importance commenced in municipal towns. Funds that in ordinary times might have been expended on s works were held in hand to "meet the exigencies of a plague epidemic" with which public bo might at any moment have to cope. Statement No. XI. of the Appendix clearly shows the he task which most of the 60 municipal towns of the Presidency have to face before their drainage water supplies can be placed on a satisfactory footing. In one direction a distinct advance is be made. It is stated that 100 Certificated Sanitary Inspectors are now in the employ of 56 muni palities, and 15 in that of a few of the District Boards. The Sanitary Commissioner takes somewhat despondent view of rural sanitary progress. After remarking that, under presen circumstances, it may be a century before any sanitary improvement on a large scale in a single rura town is effected, he writes :—"In the course of my service I have known but two instances in whic a proposal—not ultimately put into effect—was made for radical improvement of the water supply drainage of a rural town. Yet there are no less than 92 towns having a population of 7,000 an upwards in this Presidency."

12. *Summary.*—The year was a healthy one. Until its last quarter food was cheaper than in th two preceding years. It was not until the autumn rains failed, and a recurrence of scarcity wa anticipated, that prices rose. The birth-rate was the highest hitherto recorded in the Presidency This is shown to have been partly due to better registration, to increased population since last census. and to return of prosperity in succession to a season of distress. The death-rate was below that o the previous year. Registration of vital statistics is receiving ever increasing attention, but is st very defective. From cholera, small-pox, and fever there were fewer deaths than in 1898. Vaccination regained much of the ground it had lost owing to the plague-inoculation scare which had prevailed during the preceding year; but the numbers vaccinated were still below those of 1897–98. Lymph used direct from calf to arm gave the best results, and calf lymph mixed with lanoline the worst. The exceptional dryness of the year doubtless contributed to the comparative immunity of the population from malarial fevers. The deaths due to this cause were the fewest recorded since 1883. The measures adopted with the view of staying the spread of plague were, judging from results, attended with success. The need for husbanding their resources to resist possible plague invasion, prevented municipalities from embarking on new and expensive works of sanitary improvement.

No. 11.

Memorandum by the Army Sanitary Commission on the Report of the Sanitary Commissioner of Bombay for 1899.

The most striking climatic feature of the year was failure of the rainfall. This led to a recommencement of the famine conditions of 1896-97, from the effects of which the Presidency had only just had time to recover. To famine was added plague, and to these combined may largely be attributed the greater unhealthiness of the year as compared with its predecessor. Some idea may be gathered of the completeness of the rain failure from an examination of the returns given on pages 28-34 of the Report. Taking a few of the collectorates as examples it will be seen that in Khandeish only 8·54 inches of rain were recorded against an average of 42·78; of 6·5 in Kaira against 37·48, and of only 4·72 in Ahmedabad against an average of 32·29. In parts of the country, so entirely deprived of their annual complement of rain necessary for the cultivation of the soil and the growth of crops, the consequences to man and beast could not be other than disastrous. Not only grain crops and fodder, but vegetation generally would wither up, and even a sufficiency of drinking water to sustain life would be wanting owing to non-replenishment of the usual sources of supply. In September, when all hope of rain had gone, prices rose to a great height. The two millets, *jowari* and *bajri*, the staple food grains of the people, more than doubled in price. Wheat, which is too expensive a grain to be ordinarily used by the common people, also increased greatly in price, although not to so ruinous a degree as the millets. Second quality rice varied considerably in price in the course of the year, but with a markedly upward tendency. It was not until towards the end of the year that the people began to experience the full force of these calamitous conditions, and their effects will probably, therefore, be more deeply stamped on the vital statistics of the following year than on those of the year under report.

2. The small European and Eurasian populations, numbering 18,486 of the former and 8,519 of the latter, return abnormally low birth and death-rates. The recorded birth-rate amongst the former was only 11·96 and the death-rate 12·52; whilst amongst Eurasians the figures were 19·49 and 21·72. Compared with the rates recorded in the preceding year, those for Europeans show a slight decre in the case of both births and deaths, whilst those for Eurasians show a considerable increas
